SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

A MEETING of the General Committee was held on Wednesday, Oct. 12th, in the library of the Royal College of Physicians of London. Sir Thomas Barlow occupied the chair. A brief note of the meeting has already appeared in our columns.

The minutes of the last meeting were read and confirmed. Letters of regret for absence were read from the following: Mr. C. A. Ballance, Dr. J. W. Ballantyne, Mr. Gilbert Barling, Sir John Byers, Dr. W. Collier, Sir J. Halliday Croom, Mr. Clinton Dent, Dr. Gordon Dill, Mr. Frederic S. Eve, Dr. Ferrier, Dr. J. Magee Finny, Dr. G. A. Gibson, Professor J. Glaister, Dr. Dundas Grant, Mr. J. W. B. Hodsdon, Dr. W. Allan Jamieson, Mr. J. C. Keston, Sir Donald MacAlister, Professor Howard Marsh, Dr. J. Marnoch, Dr. Alexander Miles, Sir George Hare Philipson, Professor R. W. Reid, Dr. Lloyd Roberts, Mr. A. W. Mayo Robson, Professor Saundby, Sir James Sawyer, Mr. W. G. Spencer, Professor W. Stirling, Mr. John Lynn Thomas, Sir W. J. Thompson, Professor Arthur Thomson, and Dr. Wethered.

On the report of the Advisory Board, which was appointed on Feb. 7th last,[1] it was moved by Dr. PAVY, and seconded by Dr. NORMAN MOORE, that Sir Thomas Barlow be asked to become President of the next International Medical Congress. This was carried unanimously, and Sir Thomas Barlow accepted the position.

Mr. BUTLIN proposed the next resolution of the Advisory Board, viz.:—

That there be two treasurers of the Congress, of whom one should be a layman of high financial position and the other an eminent medical man.

He said that he felt considerable doubt as to the advisability of appointing a lay treasurer.

Dr. PASTEUR seconded the resolution for purposes of discussion.

Dr. NORMAN MOORE spoke against the appointment of a lay treasurer, although quite willing to invite men of science who were not medical men to take part in the work of the Congress.

Sir MALCOLM MORRIS said that the Advisory Board had had in mind the desirability of inviting laymen to bear some part of the expense of the Congress. There was no doubt that international congresses were of enormous benefit to the public of the countries where they were held, and in other countries were generally supported by public money.

Dr. KNOWSLEY SIBLEY proposed that there should be two treasurers to the Congress, and that they should both be medical men.

Dr. SAMUEL WEST seconded the amendment, which was carried.

Mr. BUTLIN then proposed that one of the treasurers be Mr. G. H. Makins, and in doing so alluded to the work performed by Mr. Makins at the previous international congress held in London.

Dr. PAVY seconded this proposal, which was unanimously carried, and it was agreed to leave the appointment of the second treasurer to the Executive Committee.

Sir RICHARD DOUGLAS POWELL proposed, Dr. HALE WHITE seconded, and it was carried, that Dr. W. P. Herringham be elected honorary general secretary of the Congress.

Dr. HERRINGHAM said that he could not accept that position without publicly expressing his great indebtedness to Mr. D'Arcy Power, who had hitherto been secretary of the National and General Committees, for his extreme courtesy and patience in explaining the details and mechanism of the work. He hoped that Mr. Power, who, he supposed, would be promoted to the Executive Committee, would continue to afford him similar assistance.

Dr. PAVY wished to add his testimony to the great amount of labour which Mr. D'Arcy Power had already for many years given to the work of the committee.

Sir HENRY MORRIS proposed—

That an Organising Committee be formed which shall select a smal Executive Committee and shall have power to add to its number.

Dr. NORMAN MOORE seconded.

The following gentlemen were appointed on the Organising Committee:—Dr. T. D. Acland, Sir Clifford Allbutt, Sir W. Allchin, Sir Charles Ball, Mr. C. A. Ballance, Dr. Freeland Barbour, Professor H. G. Barling, Sir James Barr, Dr. A. G. Barrs, Sir Wm. Bennett, Mr. G. A. Berry, Mr. L. A. Bidwell, Mr. A. A. Bowlby, Mr. Stanley Boyd, Dr. J. Rose Bradford, Dr. Byrom Bramwell, Surgeon-General A. M. Branfoot, Sir James Crichton-Browne, Dr. Alexander Bruce, Dr. Mitchell Bruce, Sir Lauder Brunton, Mr. Butlin, Dr. Dudley Buxton, Sir John Byers, Sir H. Cameron, Sir Francis Champneys, Sir Havelock Charles, Sir Watson Cheyne, Sir William Church, Mr. Andrew Clark, Professor Michell Clarke, Dr. T. C. Clouston, Professor James Craig, Dr. P. J. Cremen, Sir Anderson Critchett, Sir Halliday Croom, Dr. H. Davy, Mr. Clinton Dent, Dr. Gordon Dill, Sir Dyce Duckworth, Professor William Dyson, Mr. F. S. Eve, Mr. Harry Fenwick, Dr. Ferrier, Professor D. W. Finlay, Dr. Magee Finny, Dr. J. Kingston Fowler, Sir Thomas Fraser, Professor S. Gemmell, Dr. G. A. Gibson, Professor T. R. Glynn, Mr. R. J. Godlee, Dr. Edwin Goodall, Mr. A. Pearce Gould, Dr. W. S. A. Griffith, Director-General W. L. Gubbins, Dr. F. W. Hewitt, Dr. G. E. Herman, Mr. J. W. B. Hodsdon, Sir Victor Horsley, the President of the Royal College of Physicians of Ireland, Dr. W. A. Jamieson, Dr. Macnaughton Jones, Dr. Robert Jones, Sir Alfred Keogh, Dr. Percy Kidd, Sir Francis Laking, Mr. Ernest Lane, Dr. H. A. Latimer, Professor J. A. Lindsay, Professor James Little, Professor H. Littlejohn, Director-General C. P. Lukis, Sir Donald MacAlister, Sir William Macewen, Professor Dixon Mann, Sir Patrick Manson, Professor Howard Marsh, Dr. C. J. Martin, Dr. Charles Mercier, Dr. Alexander Miles, Sir J. W. Moore, Dr. Norman Moore, Sir Henry Morris, Sir Malcolm Morris, Dr. F. W. Mott, Mr. B. G. A. Moynihan, Professor R. Muir, Sir Shirley Murphy, Sir T. Myles, Professor J. Musgrove, Dr. A. Newsholme, Sir Christopher Nixon, Sir Thomas Oliver, Professor W. Osler, Sir Isambard Owen, Dr. R. W. Philip, Sir George Hare Philipson, Dr. F. W. Pavy, Inspector-General Sir James Porter, Sir Richard Douglas Powell, Mr. D'Arcy Power, Sir W. H. Power, Mr. J. H. Pringle, Professor J. P. Pye, Professor R. J. Pye-Smith, Dr. Guthrie Rankin, Sir James Reid, Dr. C. J. Renshaw, Mr. J. Scott Riddell, Mr. A. W.

[1] THE LANCET, Feb. 12th, 1910, p. 458.

Mayo Robson, Dr. H. D. Rolleston, Professor Ronald Ross, Dr. Amand Routh, Dr. W. Russell, Dr. F. M. Sandwith, Professor R. Saundby, Dr. G. H. Savage, Professor E. A. Schäfer, Dr. S. J. Sharkey, Professor T. Sinclair, Dr. Percy Smith, Dr. Walter Smith, Sir Wm. Smyly, Dr. Herbert Spencer. Dr. Squire Sprigge, Dr. J. E. Squire, Professor A. M. Stalker, Professor E. H. Starling, Mr. H. J. Stiles, Professor J. Swain, Sir Henry Swanzy, Mr. Charters Symonds, Dr. F. Taylor, Professor G. D. Thane, Professor Alexis Thomson, Professor Arthur Thomson, Professor W. Thorburn, Sir Frederick Treves, Dr. Logan Turner, Sir John Tweedy, Dr. J. C. Uhthoff, Dr. C. T Vachell, Dr. Norman Walker, Mr. David Wallace, Dr. W. Hale White, Dr. B. A. Whitelegge, Sir W. Whitla, Dr. Dawson Williams, Sir John Williams, and President Bertram Windle.

Sir DYCE DUCKWORTH then proposed :—

That it is advisable that distinguished laymen be invited to become members of the Congress.

This was seconded by Sir MALCOLM MORRIS.

After some discussion, in which Sir ANDERSON CRITCHETT, Dr. PASTEUR, Mr. MAKINS, Dr. SQUIRE, Mr. PEARCE GOULD, Mr. ARMIT, and Dr. BASHFORD joined, it was resolved :—

That it is advisable that distinguished laymen be invited to associate themselves with the work of the Congress, and that such invitations be in the hands of the Executive Committee.

The date of the Congress led to considerable discussion. The date proposed by the Advisory Board was from July 29th to August 6th, 1913, and a resolution to this effect was formally moved by Mr. MAKINS. He said, however, that the choice of a date was extremely difficult for several reasons, and that he hoped the General Committee would carefully consider the matter before coming to any resolution. On the one hand, the Congress could not be earlier than the date proposed, as our German colleagues could not attend if it were, and, indeed, the date proposed was earlier than that which Dr. Pavy, after conference with the German representatives, had originally proposed in the Advisory Committee; secondly, Bank Holiday came in the middle of the proposed meeting, which might possibly lead to considerable inconvenience; and a third difficulty was that the proposed date clashed with the meeting of the British Medical Association. He therefore moved the resolution rather to open the subject for discussion than to support strongly the date originally fixed.

Dr. NORMAN MOORE seconded the proposal.

Mr. BUTLIN said that he had been present when the date had been fixed by the Advisory Committee, and had himself not realised that the British Medical Association made it so regular a custom to meet at that date as he had since found was the case. He thought it would be a pity if some arrangement could not be come to with the Association.

Sir MALCOLM MORRIS pointed out that if, as was customary, royal patronage was sought for the Congress, the date of the meeting could not be settled without consulting the wishes of royalty.

Several speakers emphasised the extreme undesirability of creating ill-will in a matter of this kind and said that it was of the utmost importance that the spirit in which the Congress was to be got up should not be impaired by any feeling of hostility.

It was officially resolved, on the motion of Sir HENRY MORRIS, that this matter be not decided that day, but that it be left in the hands of the President and of the executive officers to settle the date, and that they be at liberty to receive any communications from, or to confer with, the officers of the British Medical Association.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7420 births and 4260 deaths were registered during the week ending Oct. 15th. The annual rate of mortality in these towns, which had been equal to 13·3 and 12·8 per 1000 in the two preceding weeks, rose again last week to 13·1. During the last summer quarter the death-rate in these towns averaged 11·8 per 1000, corresponding with the rate that prevailed in the summer quarter of last year. In London the death-rate last quarter, calculated on the probably over-estimated population, did not exceed 11·0 per 1000. The lowest reported annual death-rates last week in these 77 towns were 5·0 in Handsworth, 6·7 in East Ham, 6·9 in Willesden, and 7·0 in Leyton and in Walthamstow; the rates in the other towns ranged upwards to 19·4 in Burnley, 19·5 in Middlesbrough, 20·3 in Oldham, and 23·5 in Warrington. In London the reported death-rate last week did not exceed 12·8 per 1000. The 4260 deaths from all causes registered in the 77 towns last week showed an increese of 97 upon the number returned in the previous week, and included 504 which were referred to the principal epidemic diseases, against numbers declining from 720 to 497 in the seven preceding weeks; of these 504 deaths, 296 resulted from diarrhœa, 51 from measles, 47 from whooping-cough, 43 from enteric fever, 34 from diphtheria, and 33 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these diseases in the 77 towns last week was 1·6 per 1000, against 2·0, 1·8, 1 6, and 1·5 in the four preceding weeks. No death from any of these epidemic diseases was registered last week in Leyton, Wolverhampton, Handsworth, Hastings, Dewsbury, and Burton-on-Trent; the annual death-rates therefrom ranged upwards, however, to 3 9 in Burnley, 4·3 in Oldham, 4·5 in Wigan, and 5·5 in Tynemouth. The deaths attributed to diarrhœa in the 77 towns, which had declined in the six preceding weeks from 527 to 311, further fell last week to 296; in the several towns, however, they caused annual rates ranging upwards to 2·5 in Oldham, 2·8 in Wigan, and 2·9 in Burnley. The 51 fatal cases of measles were within 2 of the number in the previous week, and showed the highest death-rates, 1·3 in Hartlepool and 1·8 in Tynemouth. The 47 deaths from whooping-cough also showed a slight decline, but caused rates equal to 1·6 in Rotherham and 1·8 in Tynemouth. The deaths referred to enteric fever, which had been 38 and 21 in the two previous weeks, rose to 43 last week, and exceeded the number in any previous week of this year; they included 20 in London and its suburban districts (of which 3 occurred in Tottenham), and 2 each in St. Helens, Bradford, and Hull. The 34 fatal cases of diphtheria showed a decline of 8 from the number in the previous week; 11 occurred in London and its suburban districts, 3 each in Birmingham, Liverpool, and Manchester, and 2 in Middlesbrough. The 33 deaths from scarlet fever showed a distinct increase upon recent weekly numbers; 5 were returned both in London and in Liverpool, 3 in Stoke-on-Trent, and 2 in Manchester and Newcastle-on-Tyne. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased in the eight preceding weeks from 1423 to 1706, had further risen to 1745 on Saturday last; 234 new cases of this disease were admitted to these hospitals during last week, against 249 and 245 in the two previous weeks. The 1200 deaths from all causes in London last week included 162 which were referred to pneumonia and other diseases of the respiratory system, showing a further slight decline from the numbers in recent weeks; they were also 16 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 39, or 0·9 per cent., of the deaths registered in the 77 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Nottingham, and in 52 other smaller towns; the 39 uncertified causes of death in the 77 towns last week included 10 in Liverpool, 5 in Birmingham, 3 in South Shields and in Gateshead, and 2 each in Stoke-on-Trent, Leicester, Warrington, and Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 878 births and 468 deaths were registered during the week ending Oct. 15th. The annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 13·0 to 14·4 per 1000, declined again to 12·9 in the week under notice. During the past summer quarter the death-rate in these towns averaged 12·9 per 1000, and exceeded by 1·1 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged

from 9·8 and 10·6 in Aberdeen and Paisley to 14 9 in Greenock and 17·5 in Dundee. The 468 deaths from all causes in the eight towns last week showed a decline of 53 from the number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 83 and 69 in the two preceding weeks; of these 63 deaths, 29 resulted from diarrhœa, 15 from diphtheria, 10 from whooping-cough, 4 from scarlet fever, 3 from measles, and 2 from "fever," but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·7 per 1000, the rate from the same diseases in the 77 English towns being 1·6 per 1000. The deaths attributed to diarrhœa in the Scotch towns, which had been 51 and 40 in the two previous weeks, further declined last week to 29; they included 19 in Glasgow, 6 in Dundee, and 2 in Greenock. The 15 fatal cases of diphtheria showed a further slight increase upon recent weekly numbers; 9 occurred in Glasgow and 4 in Perth. The 10 deaths from whooping-cough also showed a further increase, including 4 in Glasgow and 3 in Dundee. Two fatal cases of scarlet fever were returned in Glasgow, and 2 of measles in Edinburgh. The 2 deaths referred to "fever" included 1 each in Glasgow and Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 61 and 72 in the two preceding weeks, declined again to 69 in the week under notice, but exceeded by 11 the number in the corresponding week of last year. The causes of 14, or 3·0 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 545 births and 374 deaths were registered during the week ending Oct. 15th. The mean annual rate of mortality in these towns which had been equal to 17·8 and 15·9 per 1000 in the two preceding weeks, rose again to 16·9 in the week under notice. During the summer quarter the annual death-rate in these Irish towns averaged 16 3 per 1000; the mean rate during the same period did not exceed 11·8 in the 77 largest English towns and 12·9 in the eight principal Scotch towns. The annual death-rate during last week was equal to 18·9 in Dublin (against 12·8 in London), 16·3 in Belfast, 14·4 in Cork and in Londonderry, 15·0 in Limerick, and 21·4 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 15·8 per 1000. The 374 deaths from all causes in the 22 town districts last week showed an increase of 23 upon the number returned in the previous week, and included 31 which were referred to the principal epidemic diseases, a decline of 9 from the number in the previous week; these 31 deaths were equal to an annual rate of 1·4 per 1000, the rate from the same diseases last week in the 77 English towns being 1·6, and in the eight Scotch towns 1·7. The 31 deaths from these epidemic diseases in the Irish towns last week included 16 from diarrhœa, 5 from measles, 4 from whooping-cough, and 3 both from diphtheria and enteric fever, but not one from small-pox. The deaths attributed to diarrhœa, which had been 45, 43, and 28 in the three preceding weeks, further declined last week to 16, of which 9 occurred in Dublin, 3 in Belfast, and 2 in Waterford. The 5 fatal cases of measles included 3 in Belfast and 2 in Portadown. Two deaths from whooping-cough were returned in Dublin and 2 from diphtheria in Belfast. A death from enteric fever was recorded in Dublin, in Belfast, and in Cork. The deaths in the 22 towns last week included 66 which were referred to pneumonia and other diseases of the respiratory system, against 54 and 44 in the two previous weeks. The causes of 13, or 3·5 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·9 per cent., while in the Scotch towns it was equal to 3·0 per cent.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1910.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·3 per 1000 of the population, estimated at 4,872,702 persons in the middle of the year. In the three preceding months the rates were 4·0, 4·1, and 3·9 per 1000 respectively. The lowest rates last month were recorded in Chelsea, the City of Westminster, Hampstead, Stoke Newington, Camberwell, and Lewisham; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, Bermondsey, and Woolwich. Scarlet fever, which had shown a decreased prevalence in the previous month, was more prevalent in September than in any other month of the current year; among the several boroughs the greatest proportional prevalence of this disease was recorded in Poplar, Southwark, Bermondsey, Lambeth, and Woolwich. The Metropolitan Asylums Hospitals contained 1630 scarlet fever patients at the end of last month, against 1358, 1530, and 1439 at the end of the three preceding months; the weekly admissions averaged 207, against 180, 190, and 160 in the three preceding months. Diphtheria also was more prevalent last month than in any previous month of this year; this disease was proportionally most prevalent in Fulham, Holborn, Finsbury, Southwark, Bermondsey, and Greenwich. There were 746 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 673, 613, and 580 at the end of the three preceding months; the weekly admissions averaged 108, against 80, 85, and 76 in the three preceding months. Enteric fever was much more prevalent than in any other recent month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Islington, Stoke Newington, Holborn, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 46, 45, and 58 at the end of the three preceding months, had risen to 141 at the end of last month; the weekly admissions averaged 32, against 8, 6, and 11 in the three preceding months. Erysipelas was proportionally most prevalent in the City of London, Finsbury, Bethnal Green, Stepney, Bermondsey, Battersea, and Deptford. The 28 cases of puerperal fever notified during the month included 3 in Fulham, 3 in Stepney, and 3 in Southwark, and 2 each in Paddington, St. Pancras, Poplar, Bermondsey, and Lambeth. Of the 11 cases notified as cerebro-spinal meningitis 3 belonged to St. Pancras, 2 to Hackney, and 2 to Bethnal Green.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the populations. During the four weeks ending Oct. 1st the deaths of 4219 London residents were registered, equal to a corrected annual death-rate of 11·9 per 1000; in the three preceding months the rates were 10·6, 10·4, and 10·3 per 1000 respectively. The death-rates last month ranged from 8·0 in Hampstead, 8·5 in the City of Westminster and in Stoke Newington, 8·6 in Woolwich, 8·9 in St. Marylebone, and 9·1 in Lewisham, to 15·2 in Poplar, 15·8 in Holborn, 17·6 in Deptford, 18·4 in Shoreditch and in Bermondsey, and 19·2 in the City of London. The 4219 deaths from all causes included 550 which were referred to the principal infectious diseases; of these, 81 resulted from measles, 13 from scarlet fever, 34 from diphtheria, 48 from whooping-cough, 31 from enteric fever, 1 from ill-defined pyrexia, and 342 from diarrhœa, but not any from small-pox or from typhus fever. The lowest death-rates from these infectious diseases last month were recorded in Paddington, the City of Westminster, Hampstead, Stoke Newington, Wandsworth, and Woolwich; and the highest rates in Finsbury, Shoreditch, Poplar, Southwark, Bermondsey, and Deptford. The 81 fatal cases of measles were 39 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Chelsea, St. Pancras, Finsbury, Shoreditch, Southwark, Bermondsey, and Lambeth. The 13 deaths from scarlet fever showed a decline of 22 from the corrected average number; of these 13 deaths, 2 belonged to Poplar, 2 to Bermondsey, and 2 to Lambeth. The 34 fatal cases of diphtheria were 17 fewer than the corrected average

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

number, and included 6 in Southwark, 4 in St. Pancras, and 3 each in Kensington, Finsbury, Lambeth, and Camberwell. The 48 deaths from whooping-cough showed a decline of 22 from the corrected average number; this disease showed the greatest proportional fatality in Fulham, Chelsea, Stoke Newington, and Bermondsey. The 31 fatal cases of enteric fever were eight in excess of the corrected average number; of these 31 deaths, 5 occurred in Bethnal Green, 4 in Stepney, 4 in Poplar, 3 in Islington, 3 in Deptford, 2 in Shoreditch, and 2 in Wandsworth. The 342 deaths from diarrhœa were less than one-half of the corrected average number; this disease was proportionally most fatal in Shoreditch, Stepney, Poplar, Southwark, Bermondsey, Deptford, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 40·6 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is notified:—Surgeon: C. D. Bell to the *Donegal*.

The undermentioned surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—William Bastian (dated August 2nd, 1908). Frank Elliott Bolton. Charles Joseph O'Connell (dated June 9th, 1910).

ROYAL ARMY MEDICAL CORPS.

The appointment of Surgeon-General J. G. MacNeece to be Principal Medical Officer of the Eighth (Lucknow) Division has been approved by His Majesty the King. Colonel T. J. R. Lucas has been transferred from Bangalore to Cherat. Colonel W. G. Macpherson, C.M.G., principal medical officer at Malta, has been appointed Principal Medical Officer of the Fourth (Quetta) Division, rendered vacant by the retirement of Colonel D. O'Sullivan. Lieutenant-Colonel J. J. Russell, from Limerick, has taken over the duties of Staff Officer to the Principal Medical Officer of the Southern Command. Lieutenant-Colonel T. W. O'H. Hamilton, C.M.G., staff officer to the principal medical officer of the Aldershot Command, has taken over medical charge of the military hospital at Warley from Major B W. Longhurst, transferred to the Western Command. Lieutenant-Colonel M. O'D. Braddell, from Lahore, has been posted for duty at Rawalpindi. Lieutenant-Colonel R. H. Hall has proceeded on two months' leave from Colchester prior to embarkation as Senior Medical Officer, Bermuda. Lieutenant-Colonel J. Maher has been selected for increased rate of pay under the provisions of Article 317 of the Royal Warrant for promotion. Major E. A. Burnside, from Golden Hill has joined for duty at Tidworth Park. Major J. McD. McCarthy has been transferred from Chester to Chapel Bay Camp. Major S. J. C. P. Perry has taken over duty at Dover from Brighton. Major C. J. Healy has been transferred from Tipperary to Fermoy. Major C. E. P. Fowler, sanitary officer, Gibraltar, has arrived home on leave. An exchange on the roster for service abroad has been approved by the War Office between Major G. T. Rawnsley and Major G. B. Carter, serving in the Dublin District. Major W. Hallaran has embarked for a tour of service in India. Major C. K. Morgan has been appointed Instructor at the Royal Army Medical Corps School of Instruction, Aldershot. Major F. J. W. Porter, D.S.O., late senior medical officer on the West Coast of Africa (Sierra Leone), has taken up duty in the London District as Recruiting Medical Officer. Major W. E Hudleston, from Gosport, has joined at Golden Hill. Captain H. R Bateman, member of the Sleeping Sickness Commission, has returned home from Uganda. Captain J. S. Pascoe has embarked from Alexandria in the *Soudan* for home. Captain J. W. West, at present serving at Queenstown, has been placed under orders to embark for India for duty in the Northern Command, embarking about Nov. 4th next. Captain A. O. B. Wroughton, from Canterbury, has joined for duty at the Military Hospital, Dover. Captain J. F. Whelan, on completion of his course for promotion at the Royal Army Medical College, London, has been posted to Manchester. Captain E. S. Worthington, specialist in advanced operative surgery, has embarked for South Africa in the *Balmoral Castle* as Medical Officer in Charge of H.R.H. the Duke of Connaught. Captain C. A. J. A. Balck has been appointed Specialist in Charge of Physical Efficiency at the Curragh. Captain N. E. J. Harding has joined at Chatham. Captain G. A. Kempthorne has been transferred from Dalhousie to Amritsar. Lieutenant F. Worthington, Haulbowline, has embarked for a tour of duty in Ceylon. Lieutenant F. H. Somers-Gardner, from Rowlands Castle, has been posted to Hilsea.

INDIAN MEDICAL SERVICE.

Colonel R. W. S. Lyons, principal medical officer of the Kohat Brigade, has been granted three months' leave. Lieutenant-Colonel J. C. S. Vaughan, superintendent of the Campbell Medical School and Hospital at Calcutta, has been appointed Civil Surgeon and posted to Bhagalpur. Lieutenant-Colonel J. G. Jordan, Officiating Civil Surgeon of Darbhanga, has been granted six months' leave home from India. Lieutenant-Colonel C. M. Thompson has been appointed to officiate as Principal of the Medical College, Madras. Major S. A. Harris, Deputy Sanitary Commissioner of the United Provinces, has taken over the duties of Sanitary Commissioner of Burma during the absence, on 15 months' leave, of Major C. E. Williams. Major S. Browning Smith, plague medical officer of the Punjab, has been selected to officiate as Sanitary Commissioner of Eastern Bengal during the absence of Lieutenant-Colonel E. C. Hare. Major T. H. Symons has returned to India from leave. Major P. Carr-White, an agency surgeon of the Second Class, has been appointed Agency Surgeon in Kotah and Jhalawar. Major S. Hunt has been granted seven months' combined leave home from India. Major E. Wilkinson, Officiating Sanitary Commissioner of Eastern Bengal and Assam, has been appointed to officiate as Sanitary Commissioner of the Punjab, in place of Colonel C. J. Bamber, who has been appointed Inspector-General of Civil Hospitals, Punjab. The services of Captain W. J. Fraser have been placed temporarily at the disposal of the Honourable the Chief Commissioner of the Central Provinces. Captain E. C. Taylor has been appointed to officiate as an Agency Surgeon of the Second Class and has been posted as Civil Surgeon of Miranshah. The services of Captain J. B. Christian have been placed permanently at the disposal of the Government of Eastern Bengal and Assam. Captain A. Cameron has been posted for temporary plague duty in the Punjab. Captain L. J. M. Deas has been appointed to the medical charge of the Mewar Bhil Corps. Captain H. C. Keates, district plague medical officer, Gujranwala, has proceeded home on one year's furlough. Captain W. L. Trafford has been selected for duty under the Civil Medical Department of the United Provinces. Captain L. Reynolds has taken over duties as Principal as well as Medical Officer in charge of the Lawrence Military Asylum, Sanawar. Captain W. J. Fraser has been appointed Civil Surgeon at Chanda, Central Provinces. Captain N. S. Sodhi has joined for plague duty in the Punjab Captain A. J. V. Betts has been appointed by H E. the Governor of Bombay to act as Deputy Sanitary Commissioner of the Western Registration District, pending the arrival of Major J. H. Marjoribanks. Captain C. A. Gill has been selected to act as Chief Plague Medical Officer of the Punjab, vice Major Browning-Smith. Captain D P. Goil has joined as Civil Surgeon of Rampore Boalia during the absence of Major A. Leventon on deputation.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank: William Darling and John M. Darling.

David Torquil Macleod Large to be Lieutenant (on probation) (dated Sept 23rd, 1910).

John Adams to be Lieutenant (on probation) (dated Sept. 19th, 1910).

TERRITORIAL FORCE.

East Riding of Yorkshire: Surgeon-Lieutenant Robert A. Draper to be Surgeon-Captain (dated Sept. 14th, 1906).

Royal Field Artillery.

1st West Riding Brigade: Surgeon-Captain John Nightingale to be Surgeon-Major (dated August 13th, 1910).

Royal Army Medical Corps.

For attachment to Units other than Medical Units.—William Murray to be Lieutenant (dated Sept. 15th, 1910). Leonard Colebrook to be Lieutenant (dated Oct. 3rd, 1910).

Attached to Units other than Medical Units.—Lieutenant Alexander T. Mulhall to be Captain (dated June 15th, 1910).

Surgeon-Major William Owen Evans, from the 2nd Volunteer Battalion, The Royal Welsh Fusiliers, to be Major, with precedence as in the Volunteer Force (dated April 1st, 1908).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Surgeon-Captain Sidney Hillier, from the 5th Battalion, The Suffolk Regiment, to be Surgeon-Captain, with precedence as in the Territorial Force (dated Oct. 15th, 1910).

TERRITORIAL OFFICERS DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Royal Army Medical Corps, Territorial Force, who have been duly recommended for the same under the terms of the Royal Warrant (dated August 17th, 1908):—Lieutenant-Colonel Thomas Horrocks Openshaw, C.M.G., attached to the Lincolnshire Yeomanry. Major William Crump Beatley, attached to the 6th Battalion, The Northumberland Fusiliers. Major John Tatham Thompson, attached to the 5th Battalion, The Welsh Regiment. Major George Williamson, attached to the 4th Battalion. The Gordon Highlanders. Major Duncan McMillan (deceased).

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Oct. 11th, Inspector-General W. H. Lloyd, R.N., in the chair, the sum of £50 was distributed among the several applicants.

The *Army and Navy Gazette* of Oct. 15th says: "With reference to some remarks made by Lord Grenfell in an opening speech at the presentation of prizes at the Middlesex Hospital on the 3rd inst. to the effect that during an epidemic of cholera in 1883 a certain amount of compulsion had to be used to get the medical officers of the army to visit the patients in the hospitals, we are authorised to state that the speaker referred to the old Egyptian Medical Department before its reorganisation by British medical officers."

ROYAL COLLEGE OF SURGEONS IN IRELAND: OPENING OF THE WINTER SESSION.—The winter session commenced on Oct. 15th, when the prizes won at the previous session were distributed by the President, Mr. Robert H. Woods, to the following gentlemen:—Barker Anatomical Prize (£26 5*s.*), T. Mather Thomson. Carmichael Scholarship (£15), M. J. Hillery. Mayne Scholarship (£8), J. S. Pegum. Gold Medals in Operative Surgery: J. S. Pegum and F. W. Warren (equal). Stoney Memorial Gold Medal in Anatomy: M. J. Hillery. Practical Histology: G. N. Smyth, first prize (£2) and medal; W. Morrow, second prize (£1) and certificate. Practical Chemistry: C. F. Coyne and M. J. Loftus (equal), first prize (£2) and medal. Public Health and Forensic Medicine: J. C. Sproule, first prize (£2) and medal; Vernon J. White, second prize (£1) and certificate. Materia Medica: M. J. Hillery, first prize (£2) and medal; Vernon J. White, second prize (£1) and certificate. Biology: L. S. O'Grady, first prize (£2) and medal; W. D. G. M'Call, second prize (£1) and certificate. Systematic Anatomy: D. J. Flanagan, first prize (£2) and medal; G. E. Pepper, second prize (£1) and certificate. Descriptive Anatomy: W. I. Adams, first prize (£2) and medal; D. J. Flanagan, second prize (£1) and certificate. Practical Anatomy: First year, W. Morrow, first prize (£2) and medal; R. A. Austin, second prize (£1) and certificate. Second year, J. C. Sproule, first prize (£2) and medal; W. I. Adams and G. E. Pepper (equal), second prize (£1) and certificate. Practice of Medicine: J. T. Duncan, first prize (£2) and medal; T. M. Thomson, second prize (£1) and certificate. Surgery: J. T. Duncan, first prize (£2) and medal; F. W. Warren, second prize (£1) and certificate. Midwifery: J. T. Duncan, first prize (£2) and medal; M. S. Moore, second prize (£1) and certificate. Physiology: J. D. Cherry, first prize (£2) and medal; A. F. Patterson, second prize (£1) and certificate. Chemistry: J. Lanigan, first prize (£2) and medal; L. E. Wigoder, second prize (£1) and certificate. Pathology: Vernon J. White, first prize (£2) and medal; T. T. Buckley, second prize (£1) and certificate. Physics: A. Merrin, first prize (£2) and medal; L. E. Wigoder, second prize (£1) and certificate.

Correspondence.

"Audi alteram partem."

THE MEANING OF THE AUDIBLE SIGNS IN MITRAL STENOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Leonard Guthrie wields so graceful a rapier and lunges so chivalrously that one feels disposed to lower one's guard to experience the pleasure of being run through by so courteous an opponent! To do so would, however, not be regarded by him as a favour, and I therefore crave your permission to endeavour to parry his thrust by replying to some of the criticism in his letter to THE LANCET of Oct. 15th on my paper under the above title which appeared in your issue of Oct. 8th. That title speaks of the physical signs audible *in* mitral stenosis, but all of which are not necessarily indicative exclusively *of* that condition.

Dr. Guthrie selects for comment one of the most interesting of these signs—namely, the apical triple rhythm met with in some phases of the cardiac action in cases of mitral stenosis, but which, I entirely agree with him, is not *only* met with in such cases. Indeed, it may frequently be observed when there is no organic valvular disease whatever, as, for example, in the ventricular dilatation of the yielding "renal heart." I also agree with Dr. Guthrie that it may frequently be observed in early childhood in connexion with mitral regurgitant disease in which there is no suspicion of valvular stenosis. When, however, he places in the same category the significance of the "presystolic bruit," if by this he means a persistent presystolic bruit, I do not see eye to eye with him. Without reference to notes I cannot state the earliest age at which I have met with mitral stenosis. Rarely, if ever, I think, as early as the fifth or sixth year of life, but I have certainly, as I think he must also have done, observed it from time to time in children not much older. Nor can I recollect having noticed a true presystolic bruit in mitral regurgitation at any age. The virtual presystolic of an enlarged heart with stretched mitral curtains, which may be met with in aortic as well as in mitral cases, I do not include in this comment.

With reference to the exception which Dr. Guthrie takes to the term "reduplicated second sound," in so far as it applies to the apical triple rhythm I am again at one with him. If he will refer to my paper he will find that that expression, used in this connexion, was employed by the late Dr. Cheadle whom I quoted without sharing his views. In the text case of my paper the true second sound was reduplicated at the base, but was at no time so heard at the apex. This only leaves as a matter of contention between us the nature of the three components of the apical triple rhythm, which, we are agreed, can by no conception be regarded as the reduplicated second sound of the heart. We are agreed that the first of these three sounds is, to quote Dr. Guthrie, "the heart's first sound," and, he adds, "often accompanied by a systolic bruit." I agree that this is so, but not in mitral stenosis. In taking the view he does he agrees with the majority of those who have considered the subject, some of whom I quoted in my paper. The same difficulty, however, presents itself as in adopting my view—namely, that, of the admittedly reduplicated second sound at the base only one portion, one sound or note, reaches the apex, and of this I have suggested the only solution which occurs to me. The second sound of the triple rhythm or canter, I believe, moreover, occurs earlier than the true diastolic phase, which follows the third sound.

Dr. Guthrie considers this third sound to be a diastolic bruit, and emphasises the point by stating that it "is direct and not regurgitant." He no doubt means by this that the bruit is never aortic, for a direct diastolic bruit must of necessity be atrio-ventricular. I agree with him that the third sound may be blunted by bruit—was so in the text case of my paper; but I fail to see how, on the purely bruit hypothesis, tone, as distinct from murmur, is imparted to the third note in the canter. There are those, moreover, who are under the impression that the apical triple rhythm is at times associated with a palpable diastolic impulse or an impulse following that of the chief ventricular systole. Of

the existence of this, except as the extra-systole of an arrhythmia, I have never been able to convince myself. I confess, therefore, Sir, with every desire to give full weight to the objections urged against the explanation of this sign given in my paper by so skilled an observer as Dr. Leonard Guthrie, that I still venture to maintain the possibility of an audible yet unregistrable ventricular extra-systole constituting the second note in the apical triple rhythm.

I am, Sir, yours faithfully,

ALEXANDER MORISON.

Upper Berkeley-street, W., Oct. 16th, 1910.

OPERATIONS AND MORTALITY.

To the Editor of THE LANCET.

SIR,—A careful perusal of your leading article in THE LANCET of Oct. 15th leads to the conclusion that in your opinion under no circumstances is it advisable that an inquiry of any kind should be made after any fatal operation. You say, "There are ever those who are ready to cry unjustifiable when some new operation is proposed or performed." On Oct. 1st last, however, you also say in a leading article on Fashion in Surgery: "There is, however, no little risk that in becoming accustomed as we are to a rapid progress in our ideas and methods we may from time to time mistake mere change for progress, the mere introduction of a new method for true advancement, a chance which is certainly increased by the fact that many procedures in surgery hold a place in our technique for a very brief period." Now, I agree in its entirety with these remarks of yours, which you further illustrate by reference to Sir James Simpson's method of arresting hæmorrhage by acupuncture, which you rightly say is now "absolutely forgotten." You also mention Calot's method of forcible reduction of angular curvature of the spine, the wonders of which "were proclaimed in nearly every medical periodical," but you further say, "Where is Calot's method now?" "Dangers undreamed of, or unmentioned, at the time soon made their appearance." "A few sudden deaths occurred and the promised improvement in the power of walking never materialised."

I would respectfully ask you, Sir, Do you not think that, say, one or two inquiries into the cause of death in some of these fatal cases would have been proper and to the benefit of the public at large? Not with a view to casting obloquy on an honoured profession, but with a view to the safety of the public and to bring about a discontinuance of a dangerous, and even fatal, operation.

Again, you further on in the same article state that: "In even more recent times still we have had gastro-enterostomy put forward as a panacea for all the ills that the stomach is heir to; for pyloric stenosis, both functional and organic; for ulcer of the stomach and duodenum; for hæmatemesis; for dilatation of the stomach, both with and without pyloric stenosis; for malignant, as well as for simple, affections of the stomach." You then go on to say in most pregnant language: "Time, which tests all our inventions, has shown that this operation does not possess all the powers attributed to it, and at the present day probably the majority of surgeons will agree that gastro-enterostomy is seldom of permanent value unless there is definite obstruction at the pyloric opening." Surely, after this scathing criticism of the operation of gastro-enterostomy, even you would admit that there was at any rate *primâ facie* evidence that, in case of a fatal termination after this operation had been performed, say for gastric ulcer or spasmodic obstruction of the pylorus, there was a reasonable ground for an inquiry, even by a coroner's jury, and that no surgeon should undertake the operation unless he was quite prepared to face an inquest.

In your article of Oct. 15th you say: "Nothing would tend to stem the onward progress of surgery so much as to make a surgeon liable to have his work tried before a coroner's jury." From this proposition I entirely dissent, and to any careful reader of your article on "Fashion in Surgery," already alluded to, it must seem clear that some such controlling influence is required to prevent what we all know is so prevalent: that as soon as any surgeon introduces a new operation a host of imitators arise, and to the great disaster of progressive surgery numerous fatalities occur, due either to the initial unsoundness of the operation, or, in other cases, to the faulty technique of the unskilful imitator.

One more quotation from the same article. You say: "We cannot imagine a tribunal less fitted for deciding questions as to the desirability of an operation, or the capability of a surgeon, than a coroner's jury." In this you are at issue with most eminent members of the legal profession. Henry Edwin Fenn, senior reporter to the Law Courts, in his work on "Thirty-five Years in the Divorce Court," p. 208, says: "Juries are generally right, often more so indeed than judges and counsel, because they judge from a common-sense point of view." Sir Edward Carson, K.C., p. 213, said: "As a rule, juries return good verdicts. I should prefer a jury's verdict to that of a judge." Chief Justice Eve, p. 214, remarked: "A jury is in general far more likely to come to a right decision than a judge." Lord Halsbury says: "As a rule, juries are, in my opinion, more generally right than judges." Lord Russell of Killowen, p. 214, "held a very strong opinion on the value of a jury as judges of matter of fact. He always thought that the average opinion of twelve men of commonsense was at least equal to the judgment of twelve judges on matters of fact."

Provided you have no objection, Sir, I would respectfully ask you to state explicitly that under no circumstances do you consider it advisable that a fatal case after operation should be the subject of an inquiry? If you would not go so far as that, will you state under what circumstances you would consider an inquiry necessary? and, as you object to juries, what tribunal you would suggest as an equitable and proper one for the purpose? This question is coming rapidly to the front and the medical faculty may as well at once make up their minds to face it. Personally, my own opinion on the matter is simple. The present coroner's inquest is all that is needed: the ordinary jury is quite able to adjudicate on the matter. If no operation were undertaken, involving any particular risk, without a deliberate consultation beforehand, with one at least, but preferably two, experienced practitioners, no operator need fear an adverse verdict of the jury in case of a fatal termination. The coroner should have the power, after considering the details of the case furnished to him, to determine as to the advisability of holding an inquest or not. This would at once prevent the holding of needless and vexatious inquests. More than this, I am of the opinion that if the people at large knew that these precautions were taken, they would more cheerfully and voluntarily resign themselves to the surgeon's hands, confident that no merely experimental operations would be undertaken, but only such as were for the undoubted benefit of the patients themselves.

I am, Sir, yours faithfully,

JAMES A. RIGBY.

Preston, Oct. 17th, 1910.

*** In the leading article of Oct. 15th we purposely alluded to the previous article of Oct. 1st. The disuse into which a new and wrong procedure falls is quite rapid, while the tendency of the compulsory inquest would be to prevent any new and right procedure ever being tried. Certainly we do not say that in no case would an inquest be justifiable where an operation had been fatal. Nor have we said that we "object to juries," but only that a coroner's jury is an unfit tribunal to sit in judgment upon surgical methods and results.—ED. L.

EFFICIENT VENTILATION.

To the Editor of THE LANCET.

SIR,—I am glad to see Dr. Leonard Hill drawing attention to the important fact first brought out by the classical experiments of Professor Flügge and his pupils Paul, Heymann, and Erclentz,[1] by Dr. Haldane,[2] and confirmed by himself—namely, that the unpleasant sensation of "stuffiness" or "closeness" induced by air of an occupied room in which the ventilation is imperfect is due to heat retention. I should like to see our sanitary authorities making practical application of this discovery for the benefit of the public health, and apparatus recording the wet bulb temperature of the air in use in all theatres and public places of assembly, such apparatus submitted to regular inspection, and a fine imposed when the wet bulb temperature of the air during occupation exceeds the limit compatible with comfort and health. Why should one be incubated when at the theatre?

[1] Zeitschrift für Hygiene, Band xlix., 1905.
[2] Journal of Hygiene, 1905.

Further, I should like to see the London County Council compel tube railways to keep their air within this limit.

But important though the wet-bulb temperature of the air may be, it is by no means the only factor of importance from the point of view of health and comfort. On the other hand, when investigating the ventilation of the Debating Chamber of the House of Commons I found reason to suspect that much of the discomfort complained of under the old conditions was due, not to excess of wet bulb temperature, but to the air having been over-dried.

In addition to those qualities of the air that appeal more especially to the physiologist, I submit that the bacteriological quality of the air of occupied rooms is also of immense moment. In this sense (*pace* Dr. Hill) the chemical index of expired CO_2 is not necessarily an index of the degree of the important bacterial impurity, for bacteria are not given off from the upper respiratory passages in ordinary quiet breathing, but only in loud speaking, coughing, or sneezing. As most of the bacteria-laden droplets of mucus sprayed out in these acts—though they may be wafted by air currents to considerable distances (70 feet or more)—sink to the floor within 10 to 30 minutes, I see no reason theoretically why with a properly designed and efficiently maintained system of downward ventilation this natural gravitation of droplets should not be made use of and accelerated, and the spread of infection thus curtailed, even though an infectious person possibly be present.

I hope the time may come when the purity of the air in public places of assembly will be as carefully looked to by the public health authorities as, say, the purity of the public water-supply is at present, and I hail Judge Rentoul's decision as of good omen. But before the air in these places, or in ships, is as satisfactory as it ought to be, the architects and engineers who design and maintain the so-called systems of ventilation in use in them will have to be in closer touch with the practical teachings of modern physiology and bacteriology than they have shown evidence of having been in the past. It would appear that too much reliance has been placed on the arrow diagram and cast-iron formulæ, and that too little actual testing of these systems has been done with the anemometer, the smoke test, and—most important of all—the human subjective test.

I am, Sir, yours faithfully,

Harley-street, W., Oct. 17th, 1910. M. H. GORDON.

To the Editor of THE LANCET.

SIR,—Dr. Leonard Hill has written to express his entire dissent from a note published in THE LANCET on Oct. 8th relating to efficient ventilation at sea. He seems to me to have misunderstood the annotation and the best proof of this is that I find nothing in Dr. Leonard Hill's expression of dissent with which I do not agree, while I also agree with the author of the annotation in question. I quite understand that in a very hot, still, and damp temperature the quick movement of air produced by a mechanical fan would be a great relief, helping the circulation of the blood and generally raising the vitality of those concerned. But ventilation was the question at issue, and this is needed in all climates. When the weather is cold not only will fans be useless but the air admitted by the ventilator must travel very slowly, for if people feel a draught they will interfere with the system of ventilation. In pointing out that the public is apt to mistake the movement of the air produced by the rotation of a fan for ventilation, it is not necessary to urge that the use of fans should be abolished. Nevertheless it seems to me that fans have nothing to do with ventilation proper.

Further, Dr. Leonard Hill urges the importance of the bacteriological rather than the chemical test for purity of air and says the open-air man is most exempt from infection. With the mud adhering to our boots we may bring into dwellings or cabins many specific germs. The other day I was in a railway dining-car where the revolving fan above created gusts which blew the menu off the table. Surely it could likewise raise the dust and bacteria from off our boots to mix them with our food. This without ventilation might be dangerous. But the dust thus raised might be at the same time conveyed out into the open air by the steady current of a well-organised system of ventilation. Dr. Leonard Hill insists on the benefit of open air, and I advocate here the necessity of efficient ventilation, so that we may have a sufficiency of open air indoors.

I am, Sir, yours faithfully,

London, Oct. 17th, 1910. ADOLPHE SMITH.

THE PROPERTY IN PRESCRIPTIONS.

To the Editor of THE LANCET.

SIR,—I have read with interest Dr. J. C. McWalter's letter in your issue of Oct. 15th, but he appears to be thinking of the law as perhaps it should be rather than as it actually is. There is nothing in English law to prevent a pharmacist selling a scheduled poison to any person who is known to him, whether such person has a medical prescription specifying it or not, although when supplying in accordance with a prescription the pharmacist is relieved from the necessity of observing certain statutory formalities which are otherwise incumbent upon him.

Again, a prescription, although generally written so that it can be compounded only by a trained pharmacist, is not usually addressed to any particular dispenser, and the fact that it has been presented for compounding to a pharmacist gives no kind of right to him to retain it. I submit that the pharmacist is an independent contractor. He is not in any sense an agent of the doctor, there being no privity of contract between them. Dr. McWalter's analogy with regard to his directions to a nurse hardly supports his contention. It is true that they were given at a certain time to a particular nurse concerning a specific patient in a known condition, but if repeated at other times for other persons, however unsuitably, I doubt if the learned doctor could obtain an injunction to, or in any other way restrain such unauthorised use of his skilled instructions.

I am, Sir, yours faithfully,

Middle Temple, Oct. 15th, 1910. H. WIPPELL GADD.

THE TREATMENT OF UTERINE FIBROIDS BY ELECTRICITY.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 15th Dr. Agnes F. Savill reports in an interesting way a case of uterine fibroid treated by X rays. It seems to me that if this treatment is to last a year it can never compare favourably with Apostoli's method by the continuous current. Lately I have had a letter from one patient and seen two cases treated by me in 1889–90—20 years ago. In two the course lasted the usual time of three months; in the third, owing to special causes, for nearly twice that time. All were cases where the prominent symptom was hæmorrhage. The first, a lady 36 years of age, was perhaps the most anæmic person I have ever seen, and was doubtless too bloodless for operation; the second was under 30 years of age, and removal of the ovaries had been recommended; and the third declined operative measures. All have now finished with menstruation, have enjoyed good health for 20 years, and in all what was left of the tumours has given rise to no symptoms.

The operation of hysterectomy, formerly so dangerous, is now so safe that I consider operation as a rule the most satisfactory treatment, but occasionally there are cases where surgical treatment is not possible, as when a patient refuses, or when it is essential that the possibility of bearing children should not be lost. In such, Apostoli's method, provided the case is a suitable one, will compare favourably with any other form of non-surgical treatment.

I am, Sir, yours faithfully,

Oct. 17th, 1910. SKENE KEITH.

CÆSAREAN SECTION SUCCESSFULLY PERFORMED TWICE IN THE SAME PATIENT.

To the Editor of THE LANCET.

SIR,—Cæsarean section is not a very common operation, so that a case where a patient underwent the operation twice successfully may be worth recording.

A Chinese woman, aged 26 years, came to hospital in 1908 in the middle of the night in labour and eight months pregnant. I assisted Dr. W. V. M. Koch (assistant superintendent) at the operation, when a dead fœtus was delivered. The woman made an uneventful recovery. In 1909 she returned four months

pregnant, when Dr. Koch dilated the os and emptied the uterus. In 1910 she returned eight months pregnant and in labour. I assisted Dr. W. B. A. Moore (assistant superintendent), who in addition to delivering a dead fœtus removed an inch of each tube. The woman recovered without a bad symptom. All diameters of the pelvis were uniformly contracted.—I am, Sir, yours faithfully,

J. BELL,
Superintendent of the Civil Hospital, Hong-Kong.

OPERATION FOR PROLAPSE OF THE RECTUM.

To the Editor of THE LANCET.

SIR,—With reference to an article by Mr. Leslie W. Dryland in your issue of Sept. 10th, p. 801, on prolapse of the rectum, and your annotation on the same, I write to state that I have performed a similar operation on two occasions.

The first was a middle-aged woman who had suffered from procidentia of the rectum for many years; it was about 6 inches long when fully down. After opening the abdomen in the left semilunar line I divided the peritoneum for about 2½ inches to the outer side of the left external iliac vessels and stripped up an outer flap of peritoneum to make a bed for the colon, removing the extra-peritoneal fat to allow the bowel to come into contact with the iliacus muscle. The edge of this flap was then stitched to a longitudinal band. This was about a year ago, and the result has been quite successful, the bowels acting normally and showing no tendency to prolapse.

Some time after performing this operation I came across a similar one described by Murphy in Kelly and Noble's "Operative Surgery," in which he speaks very highly of the procedure. Murphy makes a nest in the left iliac fossa for several inches of the bowel and stitches the peritoneal flap to the meso-sigmoid as well as to the bowel wall. The success attending the first case induced me to try it again a few months later in the case of a young woman, aged 30 years, who was three months pregnant. She had suffered terribly from the prolapse during her previous pregnancy and confinement and dreaded a repetition of it. At the time of my first seeing her the bowel always prolapsed several inches whenever she walked. A similar operation was performed and she went safely to term. During the latter months of her pregnancy there was a little prolapse of mucosa on defæcation, but if this persists it can be easily dealt with locally.

Colopexy in bad cases of prolapse is undoubtedly safer than amputation of the prolapsed bowel and appears to give quite as good results. Fixation of the bowel in the iliac fossa is unquestionably better than securing it to the anterior abdominal wall, the fixation being firmer, and there is no risk of leaving a weak scar, which is necessarily the case when the edges of the parietal peritoneum are not sutured together. I am, Sir, yours faithfully,

SIDNEY BOYD.
Chandos-street, Cavendish-square, W., Oct. 18th, 1910.

A REMARKABLE CASE OF INJURY TO THE EYE.

To the Editor of THE LANCET.

SIR,—The following account of an accident that is, I believe, unique in the history of the London and North-Western Railway Company, may be of sufficient general interest to make it worth recording.

On Sept. 22nd last an express engine-driver of the London and North-Western Railway Company came to my out-patient clinic at the Liverpool Eye and Ear Infirmary with the following story. Ten days previously he was driving the Irish Mail from Chester to Holyhead, and whilst running at a speed of 60 miles per hour down the line near Flint the window of the engine "cab" was struck by a thrush, which came through the thick plate-glass "like a bullet" and struck him in the left eye. He continued the journey to Holyhead, a distance of over 60 miles, and returned to Chester as a passenger by the next train, and had undergone some treatment at his home in that city.

I need not go into details as to the condition of the eye, but it is sufficient to say that there was a very small punctured wound in the sclerotic in the lower and outer quadrant of the eye and the whole eye was intensely inflamed. The man himself thought that this wound had been made by the bird's beak, but I strongly suspected a fragment of glass, which was not, however, proved by the X rays. The eye improved considerably under treatment, and I decided not to meddle with the wound in the hope that the small fragment of glass would be extruded. This duly happened, and a very small splinter of glass was found lying loose under the lower lid by my friend, Dr. Cyril Dobie of Chester, three days after the man left the hospital, this being the second occasion lately that I have known of a fragment of glass being extruded from the original wound by natural process.

I am told that a cracked window from the impact of a bird is not an uncommon accident to express engines, but that there is no previous instance on record of a bird coming bodily through the window, at any rate, in the history of the London and North-Western Railway. The thrush, which I suppose weighs about 4 ounces, must have been travelling at a good speed in the opposite direction, and they probably met at about 90 miles per hour. Needless to say, the thrush did not survive. I think the man's pluck in continuing the non-stop run to Holyhead is worthy of great commendation.

I am, Sir, yours faithfully,

EDGAR STEVENSON,
Honorary Surgeon, Liverpool Eye and Ear Infirmary.
Liverpool, Oct. 17th, 1910.

FIRST OPERATION UNDER ETHER IN EUROPE.

To the Editor of THE LANCET.

SIR,—I am collecting materials for a description of the first operation under ether in Europe, that performed by Robert Liston, Dec. 21st, 1846, and should be glad to hear from any surviving witness. At present Lord Lister is the only one known to me. The dresser, whose notes of the case are now before me, was Edward Palmer.

I am, Sir, yours faithfully,

F. WILLIAM COCK, M.D. Durh., F.S.A.
1, Porchester Houses, Porchester-square, W., Oct. 15th, 1910.

*** In the *Pharmaceutical Journal*, Vol. VI., No. 7, Jan. 1st, 1847, pp. 337–38, there is the record of two operations under ether by Mr. Liston at the North London Hospital on Friday, Dec. 18th, 1846. The first operation was that on Frederick Churchill, a patient with disease of the knee-joint, in which amputation was found necessary. The operation took place at 2 o'clock on Friday, Dec. 18th. The second operation was on an out-patient with a painful toe. This account was sent in by Mr. Ransome, the house surgeon of the North London Hospital. The medical staff at University College (or North London) Hospital at that time were Dr. C. J. B. Williams, Dr. A. T. Thomson, Dr. John Taylor, Dr. W. H. Walshe, Dr. E. W. Murphy, Mr. S. Cooper, Mr. Richard Quain, Mr. T. Morton, Mr. Durancé George, and Dr. Richard Quain. Surgical clinical lectures were given by Mr. Liston and Mr. Richard Quain.—ED. L.

THE QUESTION OF A COUNTERBLAST.

To the Editor of THE LANCET.

SIR,—Every member of the medical profession must receive a daily shock when he takes up his newspaper and searches for the news amongst the superabundance of quack medicine advertisements, each purporting to be an epoch-making discovery. To those whose sole literature is the newspaper such advertisements actually represent medical views. The readers believe that the statements therein made represent the progress of medical science. Surely some means can be adopted to enlighten these poor people who waste their money on quack remedies. It would be useless to attempt a crusade against these advertisements through the medium of the newspapers which publish them. Surely, however, we could reach a very large proportion of the population of our big cities by making use of the walls of the waiting-rooms of hospitals to issue a counterblast. Without mentioning any names, if this were thought inadvisable, a general warning could be posted up on these walls against the indiscriminate use of such medicines,

denying also any connexion between quack advertisements and the medical profession.

I am, Sir, yours faithfully,

County Hospital, Guildford, Oct. 15th, 1910. H. J. FARDON.

PARIS AND THE RAILWAY STRIKE.

(FROM A SPECIAL CORRESPONDENT.)

Paris during the Strike: The General Food-supply.—The Milk-supply.—The Public Danger.

THE great five days' strike is now practically over as far as Paris is concerned, but it will be some days before the total extent of the damage caused can be estimated. Already the actual loss to commerce is calculated at 50 per cent. of the ordinary daily income, and it is expected that it will take at least a week before a normal rate of business can be carried on.

The General Food-supply.

Owing to the prompt measures taken by the Government as well as by private firms, the threatened danger of a shortage in the food-supply was averted from the first. Three-quarters of the provisions needed daily by the 2,270,000 people in the city comes by rail, but in the last 20 years the river service has increased enormously, as much as 600,000 tons of foodstuff being landed yearly on the Paris quays. The authorities had not waited for the strikers before establishing a plan of mobilisation of the Seine shipping. This, with the coöperation of carts bringing in the country produce and of orders forbidding the re-expedition to the provinces of cattle already in the stockyards at La Villette, put out of the question all cause for alarm on the score of famine.

The Prefecture of the Police requested M. Guichard, the Market Commissioner, to draw up a map of France indicating the points from which the chief supplies were obtained. This map enabled the authorities to direct their energies at once on the most important sources of supplies, and by Thursday night, Oct. 13th, within 48 hours of the commencement of the strike, a system of specially guarded food trains, as well as a boat service by river and canals, was in full working order. The strikers tried to incite to revolt the carters who bring the provisions from the stations to the market, but this attempt met with complete failure, some of the men being engaged for their military service (which seems to have a calming effect), and the others being accompanied on their wagons by an armed soldier.

Prices in consequence of these able measures for the most part remained normal, the only exceptions being butter, eggs, potatoes, and fish. The rise in eggs may be accounted for by the fact that the consignments usually coming in from the foreign markets are a little late this year. The rise in potatoes is attributed to the bad harvest, which has just induced the Government to allow the importation of American potatoes, which have hitherto been excluded from the French markets on account of their fear of the potato blight. The fish market was the only one seriously affected by the strike. On the 12th only 92,000 kilos from the Dutch, Belgian, and French ports arrived at Les Halles instead of the usual amount of 200,000 kilos, and this caused a rise in price of 20 per cent. The non-arrival was not entirely due to the lack of train service, for more than one car load arrived on Thursday at the Gare du Nord, but as no one was admitted to the platforms for fear of *sabotage*, the fish was allowed perforce to rot in the station. The bakers, who number 2200, declared that they had sufficient flour in stock to furnish their customers with bread for at least 11 days, and the supply of fresh fruit and vegetables was assured, to some extent at least, by the market carts which come in from the country every day.

The Milk-supply.

The chief fear was in regard to the milk in view of the dependence on it of the children and the sick. There was a considerable shortage on Wednesday and Thursday. Of the 870,000 litres of milk that come into Paris daily, about 200,000 litres are delivered at the Gare du Nord, and on Wednesday morning the dealers had to face a shortage of 90,000 litres. About 10,000 litres were brought into the city by a temporary cart service, and the Société Maggi made heroic efforts to supply its customers by means of relays of motor drays as well as a boat service. Some of the depôts of the Société Laitière Rothschild were obliged to refuse to sell to everyone, as they had only enough for families with children. At the hospitals Cochin and Lariboisière no inconvenience was felt, but the supply for the maternity hospital Baudelocque was not enough for its needs. There was considerable uneasiness on Wednesday at the different establishments of the Assistance Publique. At the Salpêtrière the daily distribution of 300 litres of milk was reduced to 150 litres. Many of these places, such as Berck, Angicourt, Saint-Firmin-Vineuil and Aulnay-les-Bondy, are provisioned from Paris, and the Assistance Publique was obliged to send 6000 kilos of victuals to the sanatorium of Angicourt by cart and supplies of coal to Brévannes by motor-dray. On the other hand, the directors were obliged to keep in Paris two convoys of sick children ready to be sent off to the sanatoriums of Berck and Romorantin, while it was equally impossible to despatch with their foster-mothers the little ones who were to be established in homes in the departments of the Nord, Pas de Calais, and La Somme.

Dr. Variot, the physician-in-chief of the "Hôpital des Enfants Assistés," in a letter written to the *Éclair* on the 14th expressed his alarm at the non-arrival of the specially prepared (*sur-chauffé*) milk which is sent from Normandy and sold at reduced prices for the benefit of the suffering poor. At the charitable organisation of the "Goutte de Lait de Belleville" they were obliged to send away 200 poor women who had come for the daily distribution of this milk, and the authorities are to be warmly congratulated on the prompt measures taken which caused this distressing state of things to last so short a time. By Saturday morning the milk was once more arriving in the ordinary quantities, though the customers in the Fifth and Sixth Arrondissements had to wait for their supply till 9 o'clock, as the supply had been sent *viâ* the Gare d'Austerlitz instead of the Gare de Vaugirard.

The Public Danger.

In view of the different attempts which were made to endanger the public safety, it is nothing less than marvellous that the escapes have been so many and the casualties so few. Law and order have had to reckon, among the strikers, with a group of irresponsible persons openly glorying in their schemes for endangering the lives of their fellows, and no amount of foresight can entirely cope with the power for harm of the man who fears no consequences. Wherever preventive measures were possible they were quickly taken, and it is largely due to the vigilance of M. Briand and M. Lepine that France has not had to deplore more than one hideous catastrophe. During the strike the many acts of *sabotage*, usually discovered only just in time to avert a terrible accident, have been duly noted in the press. It is, perhaps, not so well known that similar attempts were being made for some months before the strike was declared. Naturally the railway companies do not care to publish abroad the details, but from time to time some indiscreet journalist elicits such facts as the signal cutting at the station of Maison Alfort or the attempted train wrecking at Jonchery, near Chaumont, when the lights were put out and a beam was laid across the track. It is also a fact well known in railway circles that in the suburbs surrounding Paris the cutting of the wires which control the signals, or the points, or the telegraph is a matter of frequent, some say daily, occurrence.

The Government has taken extraordinary precautions from the beginning. Several battalions of soldiers were quickly marched into Paris to guard the railway stations, where the police might be seen loitering about the doors in groups of from 10 to 15. Military engineers were employed in the railway electric works, and detachments of soldiers were distributed along the tracks at regular intervals to guard against the train wreckers. The two big demonstrations of the strikers which took place in Paris were so well guarded that the list of casualties was small, and even the numerous cases where the workers have been assailed by the strikers have not had any serious consequences.

On the whole, Parisians have shown a wonderful amount of *sangfroid*—from M. Lepine, strolling into the office of *L'Humanité* and gracefully introducing M. Hamard with his warrant to arrest the assembled editors, down to the little *midinette* philosophically truding the five miles to her *atelier*. Save the timid souls who thronged the big grocery shops and

repeated their large orders of last January, everyone seemed to recognise that M. Briand has had a firm grasp of the situation from the very beginning.

There is not a little irony in the fact that it is the poorer classes who have been the chief sufferers from the strike. The total losses of the Gravelines fishermen amount to £2000, while the small dealers in Paris suffered considerably from the non-arrival of their wares. The cost of living in the city being prohibitive to many workpeople, a large number live in the suburbs and come in every day by train or tramway. The failure of the electric power made the latter unavailable on many lines, and though a service of vans was soon established many people preferred to walk long distances rather than subtract from their modest daily wage the franc demanded for the drive. At the time of writing more fiendish attempts at bomb-throwing are reported. The bombs aimed at the rich have done no damage beyond wrecking a few windows. The only victim is a poor street cleaner, peaceably doing his duty, whose eyes have been badly burnt by the explosion of a package which had evidently been thrown into the gutter by someone who thought himself pursued.

The history of last week's strike offers many unnoticed details of duty unobtrusively performed. These never get such big headlines as the achievements of the strikers. But pessimists would do well to remember such instances as the linesmen who stuck to their posts and industriously helped the military engineers to repair the acts of destruction, and the driver who stayed 20 hours on his engine in order to pick up and take on to Paris three extra car-loads of provisions which he found abandoned *en route* and which he succeeded in bringing into the city with only 25 minutes' delay. The soldiers contributed not a little to the good humour of the crowds filling the stations by the willing fashion they acted as amateur porters, while if the public are thankful the strike is over the police are no less content. In reply to an inquiry as to whether the trains were running on Saturday night the tall policeman answered, "Mais oui, mais oui, ça marche bien. Il n'y a que nous qui ne marche pas, parce que nous n'en pouvons plus."

Oct. 17th.

NINTH INTERNATIONAL CONFERENCE ON TUBERCULOSIS.

(FROM A SPECIAL CORRESPONDENT.)

THIS year the International Conference on Tuberculosis held its ninth series of sessions at Brussels between Oct. 5th and 8th, under the patronage of His Majesty King Albert of Belgium.

Permanent Commissions.

The first day, devoted to the meetings of the council, though it bulked but little in the public eye, was of importance in so far that a series of permanent commissions were then organised, some of them dealing with entirely new subjects, others continuing subjects already under consideration. The President, M. BOURGEOIS, suggested that these commissions should be made permanent and that they should be asked to report at the Conference to be held at Rome next year. Six of these commissions are to collect evidence on questions of a more or less scientific character, and six are to deal with social questions. In the first group are included such questions as predisposition; channels of infection; milk; methods of treatment, scientific and vaccinal; international methods of notation; and the curative action of the solar rays. In the second group we have the part played by women in the crusade against tuberculosis; child-life and school hygiene; prophylaxis and the part played by the dispensary; the cure of tuberculosis; the public measures to be taken against tuberculosis; and the statistics of tuberculosis. On these commissions are represented, as far as possible, the different nationalities taking part in the work of the Congress. In the evening a reception was given by the Governor of Brabant, M. Beco, who was acting as the President of the Committee of Organisation.

Formal Opening of the Conference.

On Thursday morning, the 6th, the formal opening of the Conference was under the presidency of M. BERRYER, Minister of the Interior, who compared the Tuberculosis Congress to the great Peace Congress at The Hague. Both, he said, were inspired by the same profound thought, and both wished to obtain the same results; in fact, one merged into the other, and the warring of man against man was being gradually replaced, thanks to a more humane sentiment, by a movement in which all men were combining in common action against the universal ills of vice, misery, disease, and death—a sentiment that was echoed most eloquently by M. BOURGEOIS.

Discussion on the Influence of Predisposition and Heredity.

Professor LANDOUZY, introducing the first subject for discussion, the Influence of Predisposition and Heredity, claimed that these were almost as important from the practical point of view as was the bacillus of Koch itself. He maintained that the bacillus tuberculosis in the parent might act in two ways, either by direct passage from the parent to the offspring or by some toxic action on the ovum or upon the fœtus. He pointed out that these two sets of conditions were necessarily perfectly distinct, but maintained that the latter was of far more importance than the former and that it accounted for the peculiar tuberculous diathesis so frequently met with in patients the subjects of tuberculosis. He maintained that they were degenerates who often came into the world before their time, were under weight, short in stature, with thin, delicate bones, flattened chests, a skin delicate and soft, small extremities, pale and sickly face, veins very transparent, hair prematurely developed, long eyelashes, glands easily enlarged, and aspect weakly. Such features he had found specially amongst his patients and, curiously enough, these patients, with their silky, golden, or red hair, their pale, transparent skin, finely spotted with freckles, reminded him of those beauties depicted by the painters of the Venetian School, for which reason he spoke of them as of the Venetian type, or *vir rufus*. Such patients, he thought, were specially subject to tuberculosis.

M. ARLOING (Lyons), following Professor Landouzy, agreed that tuberculosis itself was seldom communicated directly from mother to child, but that a certain functional debility might be transmitted, this leaving the child open to the invasion of various causes of disease and death. In this transmission the mother played a much more important part than did the father. He thought, however, that it would be a very difficult matter indeed to demonstrate experimentally any predisposition, native or hereditary, to tuberculosis, though he believed that the offspring of the tuberculous subjects were more susceptible than those born of normal persons. This, however, was a matter that required further consideration.

Dr. AUFRECHT, speaking of the natural portals of entry, maintained that the most important of these were undoubtedly the following: the mucous membranes of the throat, especially that of the tonsils, the intestinal mucous membrane, and the epidermis. He held that the lymphatic glands played a great part in sifting out and destroying the bacilli and that as these glands became lowered in vitality they might be broken down and become scrofulous. He seemed to lay special stress on the glands and the part they played in the tuberculous process.

Professor CALMETTE, in speaking of the special predisposition of children of tuberculous parents, said that this receptivity was not specific as regards tuberculosis but applied generally to various infections and intoxications. The predisposed of the clinicians he maintained were almost invariably the subjects of infection; they were, he thought, already more or less gravely affected, especially as regards the lymphatic glands and in almost all cases reacted positively to the various tuberculin tests. Again, he found that if in place of tuberculin he injected mallein into such patients he obtained a definite loss of weight, this showing that there was a general as well as a specific predisposition. The stigmata of tuberculosis appearing at certain ages were, he thought, the result of earlier infections. Indeed, he found that of children coming up to be vaccinated 90 per cent. of those from the town of Lille were already infected with the bacillus of tuberculosis, even in cases where no definite lesions were developed, whilst in one lunatic asylum he found no fewer than 87 68 per cent. of the patients giving the skin reaction, so that if they were not already tuberculous they were certainly the carriers of the germs of the disease.

M. C. GUÉRIN agreed that amongst animals those with non-pigmented coats appeared to be more susceptible or had

a greater predisposition to tuberculosis than those of darker skin.

Dr. NATHAN RAW placed on record the result of an analysis of 232 cases of tuberculosis that had terminated fatally and found that pulmonary tuberculosis was most frequently brought about, first by direct inhalation of the bacillus tuberculosis into the bronchioles; secondly, by extension from a bronchial gland to the parenchyma of the lung, this being specially associated with or following an attack of some acute infective fever, such as measles, scarlet fever, or diphtheria; by extension upwards from the abdomen, by the diaphragm to the bronchial glands and then to the lungs; by extension downwards from the glands of the neck directly to the pleura and then to the apex of the lung; and finally, by a general infection by the circulating blood, as in acute miliary tuberculosis.

M. ROBIN believed rather in a tissue or "organ" predisposition, though he agreed entirely with the signs of predisposition given by Professor Landouzy. He laid special stress on the marked respiratory changes that occurred not only in tuberculosis but in other acute diseases.

M. RENON, in connexion with these signs or "stigmata," wished to draw attention to the low arterial tension observed in those predisposed to tuberculosis. He also wished to point out that the question of pigmentation was of the greater importance from the fact, as had been pointed out, that in cases where recovery occurred pigmentation was both rapid and complete, whilst in those that succumbed such pigmentation did not occur at all readily.

M. PIERY agreed very largely with Professor Calmette that the offspring of tuberculous parents were undoubtedly specially liable to tuberculosis and that the types of the disease in these patients were very varied. He thought, however, that a certain proportion of such offspring were actually immune, and that though immune to a grave tuberculosis they nevertheless were just the types in which the so-called stigmata of hereditary predisposition were present. Moreover, he believed with Professor Calmette, that the patients supposed to have these stigmata of the hereditary susceptibility were already suffering from the disease.

There seemed to be, amongst the other speakers, a consensus of opinion that small numbers of non-virulent tubercle bacilli taken into the alimentary canal might in certain cases act as an immunising agent, but that in larger numbers and in virulent forms they might set up typical tuberculous lesions, especially in susceptible animals. In fact, it appeared to be the opinion of some of the speakers that both immunity and predisposition might arise from the same cause, that the bacilli might, in the one case, set up a kind of negative phase or predisposition, in the other a positive phase or immunity, and that until the conditions under which these occurred had been settled it was difficult to determine the part played by heredity.

Dr. C. THEODORE WILLIAMS insisted upon the importance of predisposition and on the wisdom of trying to ascertain the conditions of the human system which caused disposition to tubercle and, conversely, those which conferred immunity from tubercle. Analysing 1000 cases of consumption that occurred in the upper classes he found that the age of attack was earlier amongst females than amongst males, and that amongst males affected by hereditary predisposition it was earlier by three years than among those free from hereditary predisposition and in females by six and a half years. Further, on analysing 400 cases of consumption taken from the out-patients of the Brompton Hospital he found that his earlier conclusion as regards the age of attack being hastened on by family predisposition was confirmed, but here the relative influence on the two sexes differed greatly from what was noted in the richer classes. Among the out-patients the age of attack was about the same for males as for females, the males being attacked earlier than among the rich, the females later. The age of attack in those free from family taint was later in both sexes, and the predisposition influence greater in the male than in the female.

One or two of the later speakers were of opinion that although the points raised in this discussion were of undoubted interest, and of course of great importance to the individual, it was perhaps inadvisable to lay much stress on this question of predisposition, except in so far as it pointed to the importance of keeping these patients out of the range of the attack of the tubercle bacillus. It was useful, of course, in both prognosis and treatment. The real campaign, however, must be carried on, and on a large scale, against the tubercle bacillus and against the conditions under which it did its work most effectively. There seemed to be some danger that the bacillus might be overshadowed in the popular mind, and it appeared to some essential that it be insisted that although the tubercle bacillus does not always set up tuberculosis no tuberculosis is ever set up without the presence of the tubercle bacillus. Were heredity to be put forward too prominently those who are dealing with the question might lose heart. At the same time, should it play any part it should involve a call to the physician to look after the building up and strengthening of his patient.

Other Discussions.

The Friday morning sitting was devoted entirely to tuberculosis in the child and in the schools, and the afternoon sitting to women's work in connexion with tuberculosis. Mrs. NATHAN RAW and Dr. J. WALKER both took part in the discussion and stated the case for England. One of the most interesting contributions made in the afternoon was that by Dr. HERMANN VON SCHRÖTTER, who spoke of the action of sunlight and high altitudes and their relation to the treatment of tuberculosis. Some of his observations on the pigmentation of the skin seemed to bear out Professor Landouzy's thesis. Dr. Schrötter believed that the pigment was formed by the cell, that it did not come directly from the blood, and that the capacity to form pigment under stimulation gave some information as to the activity and stability of the cells. He also spoke of the effect of light, especially of the ultra-violet rays, and of high altitudes upon respiration, circulation, and metabolism. Not only was tuberculosis a disease of obscurity, it was also a disease of concentration of population.

Saturday morning was devoted to the nomination of committees and to reports by the delegates from the various countries represented; from which reports it may be gathered that not only in England, Ireland, and Scotland, but in many continental countries, especially Sweden, tuberculosis was gradually being driven out.

Social Functions.

The social functions held during the Conference were almost as interesting as the scientific sederunts. The reception given by the burgomaster and the town council of Brussels in the Hôtel de Ville was as interesting from the associations of the place as from the people one met there. The annual dinner was also a great success. Amongst the congratulations and messages sent to the Conference was one from King George, dated from Balmoral Castle: "The Queen joins me in thanking you and the members for your kind telegram. We earnestly pray that successful results may attend your labours, and that a further stimulus may be given to the great international campaign that is being carried out against this terrible disease.—GEORGE, R. et I." Telegrams were also received from the Emperor of Germany, the Queen of Denmark, the Kings of Roumania, Sweden, Spain, and Norway, and from President Taft, all of them expressing keen interest in the work of the Conference. Before and after the regular meetings of the Conference excursions were made to the various Belgian sanatoriums and to other institutions in which measures are being taken to prevent the spread of, or cure cases of, tuberculosis.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Strychnine Poisoning in Liverpool.

A PROLONGED investigation by the city coroner and a jury took place on Oct. 12th into the circumstances attending the death of a man, aged 58 years, who died at his residence in the city on Sept. 20th, and on whose remains a post-mortem examination, followed by analysis, had taken place. The widow said her husband had long suffered from an affection of the eye, to which he attributed severe pains in the head, but he had thought the pains arose from brain work. The deceased had had medical advice from time to time. Latterly he had been in the habit of going for medicine to the shop of a local chemist. On the Saturday previous to his death the deceased, after complaining of pains in the stomach, obtained a draught from the chemist, and said it gave him relief. He appeared well on the following Monday,

but on returning home about 6.30 P.M. on Tuesday, he said he had "had a shocking day with his head," and he had called on the chemist who supplied him with a draught. He sat down to tea, but was shortly afterwards heard to scream. His wife inquired what was amiss, and he replied, "What has come to my head and legs?" At the deceased's request his son went for the chemist, who administered an emetic, and as the deceased continued to struggle violently he went back to his shop and fetched something in a glass. On the chemist's advice a qualified medical practitioner was called in, and while he was fetching a stomach pump and an antidote to strychnine the deceased died. The chemist deposed that he had been in business for seven years. The deceased frequently visited his shop to have prescriptions made up, and as he continued of late to complain of pains in the head the witness advised him to again consult a medical man. The deceased, however, seemed satisfied with a weakened and varied form of his own medical man's prescription made up by the witness, which consisted of a draught containing 1-40th grain of strychnine. He also was supplied with tabloids or pills which contained strychnine. In one form or other the deceased had been taking strychnine regularly for several years. If the deceased died from strychnine poisoning he must have taken more than he obtained at the shop of the witness. The deceased could have his prescriptions, which he retained, made up elsewhere, and he might have taken, in order to relieve his pain, any number of the pills, which ought only to have been administered one at a time. Mr. W. C. Williams, city and county analyst, said that he found strychnine in the stomach and liver, while there were distinct traces of strychnine in the other parts of the body subjected to analysis. The bottle containing the remnant of the draught held less strychnine in solution than the prescription, but as the draught contained an alkali, the strychnine would be precipitated and crystallised, so that it would be impossible to secure the right amount of strychnine in each dose. Hence a prescription thus made up with an alkali was extremely dangerous. The amount of strychnine found in the body was consistent with strychnine poisoning. Mr. J. E. Stott agreed with the analyst, and said that the state of health of the deceased made him an unfit subject for a powerful dose of strychnine. The coroner said there was no doubt that the deceased died from strychnine poisoning, but in all the circumstances it would be well for the jury to confine their verdict to the simple fact of poisoning elicited from the medical man and the analyst. The coroner remarked that it was evidently necessary once more to warn both the public and chemists of the danger of administering potent drugs, save on the advice of a medical man who had diagnosed the individual case. He felt he could not do better than draw public attention to the words of Mr. Justice Kennedy, who had pointed out the tendency of the poor to make the druggist into a doctor, and he warned druggists to be extremely careful, as a public duty was cast on them in supplying dangerous drugs.

Yellow Fever on a Liverpool Liner: Two Deaths on Board.

Five cases of yellow fever occurred on a Liverpool liner, which arrived in Liverpool last week, between Brazil and Portugal. One passenger and one of the crew died and were buried at sea. One patient nearing convalescence was conveyed to a Liverpool hospital for detention.

The Care of Feeble-minded Children: West Derby Guardians' New Scheme.

The West Derby board of guardians has decided to embark upon a new scheme for making provision for feeble-minded children. At its meeting on Oct. 12th it was reported that a deputation had recently visited Birmingham, and had gained much valuable information from their inspection of institutions provided by the three Poor-law unions of that city for the care of mentally defective children. The deputation had been greatly impressed with the splendid arrangements made by the Birmingham Poor-law authorities for looking after this unfortunate class of people, and in the West Derby Union they had resolved to make a start on similar lines by adapting one of the cottages at the Fazakerley Cottage Homes to this purpose. Later it was hoped to extend the scheme by providing if possible an institution such as the colony they had seen at Birmingham for epileptics and the feeble-minded. This scheme was the most important that the West Derby board of guardians had yet taken in hand, and it was hoped that the committee would not be tied down to any hard-and-fast regulations, but before any serious expenditure was entered into the board would be made aware of it. The project was heartily endorsed by the board.

Public Hygiene in St. Helens.

At the meeting of the St. Helens health committee held on Oct. 12th the town clerk said that a clause was being put into the new Parliamentary Bill prohibiting spitting in the streets by any person suffering from pulmonary tuberculosis. The corporation had already power to make a by-law to the effect that "No person shall spit on the floor, side, or wall of any public carriage or of any public hall, public waiting-room, or place of public entertainment, whether admission thereto be obtained by payment or not, or in any enclosed or covered market." It would strengthen the hands of the committee if the clause were put in the Bill. The committee agreed thereto.

Oct. 17th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Report on Ptomaine Poisoning at Wrexham.

THE medical officer of health of the Wrexham urban and rural districts (Mr. D. Llewelyn Williams) has reported upon the cases of food poisoning which occurred in Wrexham and the adjoining district in August last. On the 6th and 7th day of that month about 100 persons were suddenly attacked with acute intestinal symptoms, including abdominal pain, vomiting, and diarrhœa, and in some cases there was collapse. Five of the patients died. It was ascertained that all those attacked had eaten a portion of pork pies purchased at one particular shop. Samples of these pies have been examined in the bacteriological laboratory of the Royal Institute of Public Health, and Professor W. R. Smith has reported that there was obtained from them by direct cultivation an organism which both from its varied cultural characteristics and its agglutination results was undoubtedly either the paratyphoid bacillus or the bacillus enteritidis of Gaertner. The same organism was also found in the viscera of one of the patients whose illness terminated fatally, and in the blood of three persons who were in close attendance on this patient and who were attacked with symptoms similar to those in the earlier cases. The organism was also found in the fæces of a man who worked in the shop in which the pies were made. A search for metallic substances in the pies gave negative result.

Cardiff Tuberculosis Dispensary.

A scheme for the voluntary notification of phthisis has been in force in Cardiff for some time, and efforts in other directions have been made to lessen the incidence of the disease. On Oct. 2nd there was opened a municipal dispensary for the treatment of tuberculous patients. It is situated in the basement of the City Hall, where there have been set aside a waiting-room, a consulting room, a weighing room, and a dispensing room. Already some 50 patients have attended, most of them being residents in Cardiff, but a few have come from the adjoining rural districts. The institution is open from 6 to 8 on the evenings of Monday, Wednesday, and Friday, and is under the charge of the assistant medical officer of health (Mr. E. Fairfield Thomas), who is assisted by a nurse who acts as dispenser. Every effort will be made to get in touch with the early cases of consumption through the corporation health visitors.

Open-air School in Monmouthshire.

Early in the present year the Monmouthshire education committee erected an open-air school with accommodation for 40 children at Aberbargoed in the Rhymney valley. It is situated on the side of the hill at an elevation of 700 feet above sea level. In the month of March children who were anæmic or debilitated and who were likely to benefit by the change were selected from the lower standards in the neighbouring schools. After attending the school for several months a marked change has been noticed in them, and the head teacher has reported that they now show an eagerness to join in games where hitherto they had preferred the shelter

of the school walls, and there is a gradual displacement of shyness or of indifference for a brighter and more cheerful countenance. The school curriculum has been modified so that the lessons are shorter, and rambles are taken for nature studies. Twice a day, at 11 A.M. and 3 P.M., there is an interval of five minutes when each child has a glass of milk, most of the parents contributing towards the expenditure involved.

Oct. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

New Clinical Medicine Laboratory of Edinburgh Royal Infirmary.

ON Oct. 13th Sir Thomas Clifford Allbutt, Regius Professor of Medicine, University of Cambridge, formally opened the new laboratory of clinical medicine of the Royal Infirmary, Edinburgh. The ceremony took place in the large theatre of the infirmary. Professor Rankine, in the absence of the Lord Provost, presided. Those present included managers of the infirmary, the Principal and professors of the University, staff of the infirmary, and general public. At the outset Dr. George A. Gibson, with whom originated the idea, explained that through the extreme generosity of an anonymous donor a considerable sum of money had been placed at his disposal for the establishment of a fully equipped clinical laboratory, fitted with the latest apparatus for the study of the phenomena of the heart and circulation and for furnishing graphic records of these phenomena, and with the most recent appliances for the use of the X rays. In declaring the laboratory open, Sir Clifford Allbutt deprecated the tendency to dissociate pathology and clinical medicine, and welcomed such a laboratory as a step towards the integration of pathological research with clinical medicine. Pathology, speaking broadly, was merely one side of medicine, and nothing but evil and arrested progress could result from their separation. The pursuit of medicine, of all callings in life, was the most difficult. Medicine was not an exact science; our knowledge of it was constantly being added to, and the acquisition of this knowledge at all times presented very considerable difficulties, and new facts were only acquired gradually and laboriously. Such a laboratory as was now being added to the infirmary formed one of the means for acquiring such fresh knowledge, and so helped further to forward treatment and relieve suffering. The managers of the great hospitals in the kingdom, he felt sure, were beginning to see that many of these investigations which might seem to them fanciful or merely academic had enormously enlarged medical knowledge within the past few years. These investigations were not completed, but were constantly being added to, resulting in very great benefits to the sick with whom they had to deal. The apparatus that had been put down in the new laboratory recorded those electrical changes in muscle that were proving to be of the greatest importance in investigating the state of the heart. They had for the first time some definite means of ascertaining precisely the functional value of its muscle. After the opening ceremony the company proceeded to inspect the new laboratory. The infirmary managers have provided two rooms on the medical side of the infirmary and close to the medical wards, where patients can be readily conveyed for observation and treatment. In one room there has been installed a powerful apparatus for the screen examination by X rays of various internal diseases. It is so fitted up as to afford perfect security to the patient and observers from any injury by exposure to the rays, and has attached the most modern appliances for moving the patient into convenient positions for examination with the least possible discomfort. The other room contains various instruments for obtaining graphic records of the movements of the heart, a recording galvanometer that registers the electric currents produced by each beat of the heart, various forms of kymographs for the registration of pulsations and other movements which cannot be studied accurately except by graphic methods, and an instrument for the study of small changes in electric potential in living organs. There are also a number of appliances for the study of blood pressure. In addition, in the clinical medicine theatre, there has been fitted up an elaborate Leitz projection lantern for demonstrating microscopic specimens, solid objects, and diagrams, as well as ordinary lantern slides.

Edinburgh Royal Medical Society.

The 174th session of this society was opened on Oct. 15th by Sir Clifford Allbutt. He addressed the students on blood pressure and arterial disease. He first of all traced our knowledge of the subject from the introduction of instrumental means of investigation. He then discussed the production of arterial disease and its relationship to Bright's disease, pointing out the necessity for clearly distinguishing and separating the two. He showed how abnormal blood pressure in course of time, and as the result of peripheral constriction or resistance, produced definite and permanent changes in the arteries. Many other causes might have the same effect. But, on the other hand, elevated blood pressure did not necessarily follow arterial disease. Many cases of calcareous degeneration of arteries showed little or no elevation of blood pressure. Finally, he discussed the condition of elevated blood pressure, which he has called hyperpiesis, pointing out that it was permanently curable, but that it might and did recur, and if it recurred often or was untreated from the start it ultimately ended in arterio-sclerosis. Along with suitable dietetic restrictions he considered calomel the effective therapeutic measure for the treatment of the condition.

Death of Dr. D. H. Stirling, Perth.

Dr. David Halket Stirling, one of the oldest members of the medical profession in Perth, died on Oct. 14th, at his residence, Kinnoull Cottage, Perth. The deceased gentleman, who was in his eighty-first year, was born at Guildtoun, near Perth, and studied medicine at Edinburgh University and in Paris and Vienna. He started practice in Perth about 55 years ago. Dr. Stirling was very well known and highly respected by the citizens of Perth and district.

Aberdeen Parish Council Medical Officership.

The Aberdeen parish council met on Oct. 11th. The inspector said that there were no applications for the post of poorhouse visiting medical officer. In reference to the question asked at a previous meeting as to the power of the parish council to dismiss its resident medical officer, a telegram had been received from the Local Government Board. It said: "The poorhouse medical officer cannot be dismissed without the sanction of the Local Government Board." After much discussion it was finally decided to leave the question of the visiting medical officership to the next council. At the same meeting a letter was read from Dr. W. J. Byres, who recently held the office of poorhouse visiting medical officer, in which he complained of a remark made by one of the council at a previous meeting in reference to his report. The chairman pointed out that the rest of the council did not entertain the same views as the member who had made the remark, and the letter was allowed to lie on the table. A list of unvaccinated children was submitted, and the chairman stated that there were some 19 objectors who had not lodged objections with the registrars in time. The Local Government Board was anxious to prosecute in those cases. It was decided by 16 votes to 15 not to prosecute.

Honour to Professor Ogston.

The ceremony of presenting the portraits of Emeritus Professor Alexander Ogston took place in the Picture Gallery of Marischal College, Aberdeen, on the afternoon of Oct. 14th, one portrait being handed over to the University, the other being a gift to Professor Ogston's family. The ceremony was largely attended by the medical profession; there were also representatives of the Senatus and University Court and of the University, and many others. The portraits have been painted by Mr. Fiddes Watt, A.R.S.A. Professor Findlay presided, and said that when Professor Ogston retired from the chair of surgery last year it seemed to some of his old pupils and professional friends that it would be a fitting thing to promote a memorial of his long and distinguished career as a teacher of surgery, and accordingly, in May last, a committee was formed to carry out this object. The proposal was cordially responded to in all quarters. The Right Hon. Robert Farquharson of Finzean presented the first portrait to the University, and in the absence of Principal George Adam Smith, Professor Matthew Hay accepted it on behalf of the University, in the course of his remarks saying that no one had done more than Professor

Ogston to increase the educational efficiency of the University and to advance its reputation throughout the world. "We are all of us—teacher, graduate, and student alike—proud of Professor Ogston. He is one of our own, the son of a distinguished professor of this University, a brilliant student in its medical faculty, and, finally, the eminent occupant of its chair of surgery." Dr. Farquharson afterwards presented Professor Ogston with the second portrait. Professor Ogston, in the course of his reply, stated how highly he valued the appreciation of his colleagues and pupils. He had been given a place in the Pantheon of the University, which, however little he might deserve, he most deeply appreciated. He remarked upon his close connexion with the University, for at the house which stood where the chemistry laboratory of the University now stands, his first lessons in walking were obtained in the quadrangle of Marischal College. Graduating in medicine and surgery when two days under age, he began at the age of 22 the connexion with the medical school which had not hitherto been interrupted, unless interrupted now. "All that I have I owe to the College and the University, and no one can wonder that my love for it should be so deep, and hence the value of what you have conferred upon me must be tenfold greater than it otherwise would have been." Professor J. Marnoch proposed a vote of thanks to the committee and to Dr. J. Mackenzie Booth, who had spared no effort to achieve success. Dr. Mackenzie Booth replied, and intimated that a photogravure of the University portrait was being prepared and was to be sent, with a *résumé* of the proceedings on this occasion and a list of subscribers, to all those who contributed to the testimonial. He added that a considerable surplus of money was to be handed to the University to provide an annual prize of instruments for the best student in the senior section of the surgery class, to perpetuate Professor Ogston's memory in future generations of the students of his Alma Mater.

Royal Aberdeen Hospital for Sick Children.

A special appeal has been issued by the directors of this hospital for funds to provide a larger building on a new site. The new building will require to contain at the very least 100 beds, and it is estimated that the erection of such a building, capable of ready extension for future requirements, on a suitable site will cost from £30,000 to £35,000. Her Majesty the Queen has been graciously pleased to become patroness of the institution, and it is considered that the new hospital building will form an appropriate and fitting memorial to the late King.

Oct. 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Ireland.

Dr. J. Hawtrey Benson has been elected President of the College for the ensuing year.

Royal Academy of Medicine in Ireland.

The annual meeting of the Royal Academy of Medicine in Ireland was held on Oct. 14th at the Royal College of Physicians. The report stated that the number of Fellows was 184, of Members 22, and of Associates 9. The credit balance at the bank was £255 9*s.* 7*d.* The annual elections were held, special interest being taken in the election for the general secretaryship consequent on the resignation of Dr. James Craig. No less than six candidates offered themselves, of whom Professor J. A. Scott was elected. The other elections resulted as follows:—Secretary for Foreign Correspondence: Sir John Moore. Medical Section: President, Sir John Moore. Surgical Section: President, Mr. R. H. Woods, P.R.C.S.I. Obstetrical Section: President, Dr. H. Jellett. Pathological Section: President, Dr. A. H. Benson. Section of Anatomy and Physiology: President, Dr. E. P. McLoughlin. Section of State Medicine: President, Dr. E. J. McWeeney. A resolution was adopted that a quinquennial enumeration of the population is most desirable, and recommending the Academy to make representations to this effect "to the Government, and to invite the assistance of the Irish Universities, the Royal Colleges, the Irish Medical Association, and such bodies as the Royal Dublin Society and the Dublin Sanitary Association in attempting to attain so important an object."

Memorial to Dr. Conolly Norman.

Last Tuesday being St. Luke's Day the memorial tablet to the late Dr. Conolly Norman erected in St. Patrick's Cathedral was unveiled by His Excellency the Lord Lieutenant. The memorial, which is erected in the north choir aisle, consists of a bronze relief portrait of Dr. Norman by Mr. J. M. Carré, set in a niche of Bath stone designed by the late Sir Thomas Drew. The plaque is surmounted by a heraldic device in bronze, also by Mr. Carré; while the lower panel of the niche contains a bronze plate bearing the inscription. Later in the afternoon of the same day a deputation of the subscribers presented to the Royal College of Physicians a portrait in oils of Dr. Norman.

Opening of New Dispensaries at Jervis-street Hospital.

Lord Aberdeen attended at Jervis-street Hospital last Monday to declare the new dispensaries open. The Charitable Infirmary, Jervis-street, is the oldest of the general hospitals of Dublin. For some years the out-patient rooms, which were then situated in the basement, were recognised to be inadequate, and the managing committee at length found itself able to undertake rebuilding, with the result that a fine suite has been erected consisting of large, airy reception-rooms for medical and surgical cases and a number of smaller rooms for dealing with special conditions. Some of the funds have been provided by the Pembroke Charities Trustees, but the remainder is still to seek.

Accident to Mr. R. L. Swan.

A serious accident occurred last Saturday to Mr. R. L. Swan, surgeon to Dr. Steevens' Hospital, and ex-President of the Royal College of Surgeons in Ireland. While cycling in the streets of Dublin he fell off his machine, and the wheel of a van went over his chest, breaking three ribs. His many friends will hear with pleasure that his progress has been satisfactory.

Irish County Asylums and the Reduced Grants.

The greatest dissatisfaction has arisen throughout Ireland in regard to the reduced Treasury capitation grants to the county asylums. For instance, in County Cavan the deficit, as compared with the estimate, is £1631 13*s.* 9*d.*; in County Monaghan, the deficit is £1360 2*s.* 9*d.*; in County Sligo, the deficit is £1187 5*s.*; and £996 10*s.* 2*d.* in County Leitrim. In County Tyrone the reduction is £1728; in County Derry, £1100; and in County Fermanagh it is £770 0*s.* 8*d.* It would appear that in the past the Treasury has given a capitation grant of 4*s.* per week to Irish asylums, which was met by an Imperial grant of £79,000 per annum, together with licence duties—not whisky duties. It is strange there is no reduction in this grant towards England and Scotland. It would seem the grant in Ireland has been reduced on account of the increased expenditure in asylums which the county councils made on the faith of getting this capitation allowance. The inadequacy of local taxation to meet its liabilities is said to be due to causes over which the local authorities have no control, such as (1) increase of lunacy, (2) falling-off of revenues from sources of income on that account; (3) a large portion of expenditure on asylums is under the head of repayment of loans which were borrowed under the direction of the Board of Control with the consent of the local authorities; (4) increased cost of upkeep through general rise of market prices; and (5) most of the inmates of asylums are dangerous lunatics committed by magistrates whose admission is as compulsory on committees of lunatic asylums as on governors of jails. Very strong resolutions are being passed by the asylum boards all over Ireland, protesting against this action of the Treasury, which the Chief Secretary will have to explain when Parliament opens. It is said the deficit in Belfast will be £2000, and that there will this year be entailed on the ratepayers of Ireland a burden which is estimated as £62,000 in consequence of the falling short of what is known as the local taxation account—that is to say, the proceeds of licences and of the liquor duties—upon which the charges to pay on each patient in Irish asylums one-half the cost of maintenance, or 4*s.* in the £, were laid. Under the Local Government Act, not only this capitation grant but half the salaries of medical officers and certain other local grants were charged upon the local taxation fund derived from licences and from liquor taxes. It is clear some arrangement should have been made to anticipate this shrinkage of

revenue. The Chief Secretary is to meet a deputation on Oct. 24th in reference to the matter.

The King Edward VII. Memorial in Belfast.

The sum now subscribed for the King Edward VII. Memorial (which is to take the form of an additional block to the Royal Victoria Hospital) amounts to £13,046.

Oct. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Congress of Surgery.

THE first subject of discussion at the recent Congress of Surgery was the Surgical Treatment of Exophthalmic Goitre. It was introduced by M. Delore, who dealt chiefly with the various methods of operating, and by M. Lenormand, who described the indications for surgical treatment and the results that had been obtained. Sir Victor Horsley explained the views of English surgeons on several points of the question. He said that in the majority of cases medical treatment was insufficient. When a patient had been under observation for six weeks, and had undergone medical treatment without benefit, an operation might be undertaken. M. Forgue of Montpellier said that in his opinion an operation ought not to be too long delayed. M. Girard of Geneva spoke only on the application of thyroid ligatures previous to a more extensive operation. M. Ceci of Pisa advocated local anæsthesia in operations on the thyroid gland. The subsequent speakers were M. Tavel, M. Doyen, M. Jonnesco, M. Alessandri, M. Morestin, M. Bérard, and M. Van Stockum, the latter of whom was emphatic as to the danger of general anæsthesia, and said that he always preferred local anæsthesia in these operations. M. Broeckaert of Gand said that in Belgium operations for exophthalmic goitre were not common. M. Lucas-Championnière spoke of cerebral decompression by opening the cranium. He said that his numerous operations had led him to think that this valuable procedure had not been sufficiently taken advantage of. The operation which he performed was a very simple one and not serious; it consisted in trephining, enlarging the aperture with a gouge, and incising the dura mater. M. Girard described the operative treatment of serous meningitis. The next subject of discussion was the Surgical Treatment of Duodenal Ulcer. It was introduced by M. Ricard and M. Pauchet, who confined their remarks to the primary ulcer of the duodenum, which was the classic form of the disease, whereas the secondary ulcer presented no clinical interest. The diagnostic points were the pain and the previous history of the illness. The most frequent complication was perforation, which might be either acute, subacute, or chronic. The treatment of perforation consisted in lateral laparotomy and suture of the ulcer in two layers with drainage of the subhepatic space and the pouch of Douglas. An operation was the only efficacious treatment of duodenal ulcer, gastroenterostomy being the most advisable procedure. M. Ricard and M. Pauchet concluded by saying that the French statistics of these operations did not show brilliant results, probably because the operators have not had much experience of duodenal surgery. M. Tédenat, M. Hartmann, M. Jonnesco, M. Delaunay, M. Lardennois, M. Monprofit, and M. Boeckel explained their views and mentioned the results of their operations. M. Jeannel introduced a discussion on the Immediate and Remote Effects of Cutting Operations in the Treatment of Varix of the Lower Limb, and the topic was continued by M. Mauclaire, who described the treatment of the principal complications of varix—namely, varicose ulcers, phlebitis, and rupture of the enlarged veins. M. Ceci, M. Willems Boeckel, M. Villar, M. Tavel, M. Bérard, M. Alessandri, M. Reymond, M. Sabadini, M. Lardennois, M. Paul Delbet, M. Viannay, M. Rémy, M. Durand, and M. Poussié also took part in the discussion.

Poisoning by Decoction of Poppy-heads.

At a meeting of the Society of Legal Medicine held on Oct. 10th Dr. Dutilleul and M. Bonn, a chemist, presented a communication in which they stated that the employment of a decoction of poppy-heads was very common in the north of France and that death was unfortunately sometimes due to this cause. They reported a case occurring in the vicinity of Lille in which an infant aged 4 months had in the course of eight days taken an infusion of three poppy-heads in a litre of water. The child died and the necropsy showed several of the ordinary indications of opium poisoning but no evidence of organic disease to which the fatal issue might be attributed. On analysis the viscera were found to contain a dangerously large amount of alkaloid. In view of the risks attendant on this method of treatment Dr. Dutilleul and M. Bonn expressed surprise that poppy-heads should be freely sold not only by druggists but even herbalists and grocers, and they recommended the introduction of restrictions.

Treatment of Tuberculosis on the Mediterranean Coast.

At a meeting of the Academy of Medicine, held on Oct. 11th, M. Debove read a report on a communication by M. Révillet showing the results of the treatment of infantile tuberculosis in the Dollfuss Sanatorium at Cannes on the Mediterranean. In this institution children from Geneva suffering from tuberculous disease of the bones, joints, and glands are received during winter. Before leaving Switzerland they are examined by a commission of which M. d'Espine is the president, and they are again examined on their return. The commission has found that excellent results have been obtained from the treatment which includes daily sea-bathing and heliotherapy.

Granular Conjunctivitis.

An epidemic of granular conjunctivitis which has prevailed for some months in a certain *quartier* of Paris is an obvious danger to the public health. This condition, although extremely contagious and difficult to treat, is not included among the diseases notification of which is compulsory. The municipal councillors of several arrondissements of Paris recognise that the matter is serious and will question the prefect of police on the subject. Dr. Dubief, principal inspector of epidemic diseases in the department of the Seine, is also announced to present a report on the circumstances. The majority of the patients are Jews and Armenians coming from Syria, Judea, and Egypt. Deportation of the patients would be the most efficacious measure but would be rather troublesome, as they are from 250 to 300 in number, and it would also be necessary to prevent them from returning. In this difficulty the best courses would be (1) to compel all patients of foreign origin and under the supervision of the police to undergo regular treatment under pain of deportation, and (2) to prevent the spread of the contagion by giving some instruction in hygiene to all the French people who are brought into contact with the patients through being employed in the lodging-houses where they live.

Oct. 18th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Malaria Prevention in the United Provinces.

DURING the course of last year instructions were issued from the office of the Sanitary Commissioner, United Provinces, to the municipal boards through commissioners of divisions regarding the treatment of tanks and other water surfaces with kerosine oil with a view to the reduction of malaria. These instructions have been carried out in several localities, while in certain others surface drainage has recently been improved and insanitary pits and hollows have been filled up with a view of diminishing the breeding places of mosquitoes. Quinine has also been distributed gratuitously in many districts. As the fish known as "millions" are reported to be very voracious and to feed on the eggs, larvæ and pupæ of mosquitoes to such an extent as to render it impossible for these latter to breed in the waters frequented by the fish, a supply of them was obtained in November last from England through the kindness of Lieutenant-Colonel J. J. Pratt, I.M.S., and Major W. Selby, I.M.S. They are for the present being kept in the Zoological Gardens, Calcutta, and are to be experimented with as soon as they have increased to sufficient numbers.

Beri-beri and Rice.

The conclusions now so generally accepted that beri-beri is a disorder of nutrition associated usually with a diet of which white, or "over-milled," rice is the principal constituent will probably have an important effect on the rice

trade, and rice millers will have to modify certain of their processes. According to a letter from the Government of Burma to the Burma Chamber of Commerce, the Hong-Kong administration is to consider measures for the exclusion of polished rice from their territories, and it is not unlikely that other governments will be inclined to a similar policy. The Burma Chamber of Commerce is making inquiries on the subject, so that rice millers may be warned to take steps in time to prevent the large rice export trade of the province being injured.

A Pasteur Institute for Bombay.

The Government of Bombay in a note to the municipal Commissioners and the chairman of the Bombay Port Trust, in favour of the establishment of a Pasteur Institute in Bombay, to be located at Parel, states that the cost of such institute would be a legitimate charge to municipal revenues. As, however, the Parel Laboratory as a Government institution affords facilities for the establishment of the proposed branch on an economical scale, and as it would be for the treatment of patients coming from outside of Bombay, it is thought that it would be inequitable to expect the municipality to meet the whole of the expenditure incurred at Parel. The services of the superior medical staff already employed and trained at the laboratory will be available for bacteriological and other work in connexion with the antirabic treatment, thus effecting considerable reduction in the expenses of the institute. The services of the clerical and other establishments at the laboratory will also be utilised without much extra cost for the work of the proposed branch. It is estimated that the maintenance of the branch institute in conjunction with the Parel Laboratory will cost from a minimum of Rs. 16,000 to a maximum of Rs. 31,000 a year, according to the grade of medical staff employed. The average may be taken as about Rs. 20,000 a year. The government proposes to lay the scheme before other local bodies in Bombay and the Mofussil, and the benevolent public will also be asked to subscribe.

The National Medical College of India.

In response to invitations issued by the President of the Board of Governors of the National Medical College of India to meet Sir Lawrence Jenkins, Chief Justice of Bengal, a large and representative gathering assembled at the College Hall, Calcutta, recently. Sir Lawrence Jenkins, on arrival, inspected the college and hospital attached to the institution, and was favourably impressed by all he saw. The superintendent of the college then read an address of welcome to the Chief Justice, in the course of which he said that the college was intended to be an auxiliary to official colleges. He said that a late Lieutenant-Governor, referring to the institution, stated he was very strongly in favour of a medical institution apart from the official medical college. Sir Lawrence Jenkins was convinced a separate non-official medical institution will lead to much better organisation of medical teaching in Calcutta. Their efforts had not been fruitless; their scholars hailed from all parts of India. Students were carrying out a noble mission, for they go right into the interior and carry into remote Mofussil villages the blessings of modern science. Their professors were men who have had a brilliant training in Europe under teachers of world-wide fame. The locally educated professors were also men of high attainments, with special knowledge in their respective departments. All of them are giving their gratuitous services to the institution, receiving nothing more than mere *gharri* (carriage) hire. The school attached to the college was making itself greatly useful. The out-door department gave relief to about 20,000 patients yearly. The indoor department was very much in need of additional accommodation. Pressure on the beds had been so great that they had been obliged to refuse many applications for admission. They were also endeavouring to revive the ancient Ayurvedic system of medicine on a modern basis by infusing into it the elements of modern scientific treatment. An address was then presented to the Maharaja of Cossimbazar for his interest in all movements and objects for the well-being of the citizens. A suitable reply was made. Sir Lawrence Jenkins next announced that the Maharaja of Cossimbazar had promised a donation of Rs.6000 and the Maharaja of Darbhanga Rs. 2000 towards the erection of a suitable building for the college.

The St. John Ambulance Association.

An account of the proceedings at the annual meeting in Simla of the Indian branch of the St. John Ambulance Association has just been issued. The report presented to the meeting by the honorary secretary, Major R. J. Blackham, R.A.M.C., bears witness to the phenomenal progress made by the branch during the past year. In March of the previous year there were, even on paper, but nine centres of the association. Now there are seven strong provincial and six State centres, besides various district centres, a Bengal coalfields centre, and centres on nearly all the chief Indian railways. In almost every direction, and especially on the railways, due in this case largely to the great interest displayed in the work of the association by Sir Trevredyn Wynne, chairman of the Railway Board, Major Blackham finds cause for much congratulation at the record of progress made. In fact, to quote his own words, "The work of the Association is now being carried on enthusiastically in all parts of this vast Empire, and there is every reason to hope that in a very few years there will hardly be a hamlet from Jamrud to Trichinopoly, and from Bombay to Bhamo, where its courses of instruction will not be known and appreciated."

Sept. 15th.

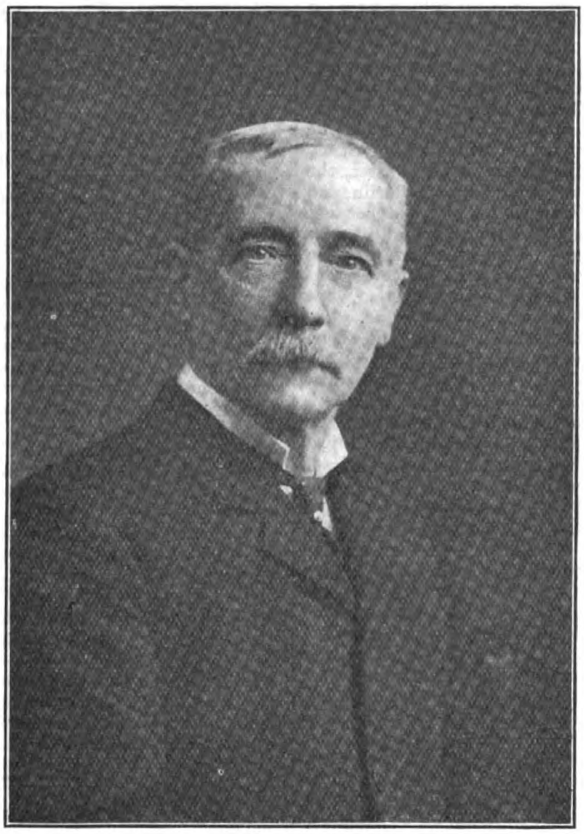
AUSTRALASIAN MEDICAL CONGRESS.—The ninth session of this Congress will be held in Sydney during September, 1911, under the Presidency of Mr. F. Antill Pockley. The session will commence on Monday, Sept. 18th, and end on Saturday, Sept. 23rd. The Senate of the University of Sydney has kindly granted the use of its buildings and grounds, and the Government of New South Wales has given its countenance and support to the Congress. The following are officers of Congress:—President: Dr. F. Antill Pockley. Treasurer: Dr. S. H. MacCulloch. General Secretary: Dr. Arthur Palmer. Associate Secretary: Mr. A. J. Brady. The following are Vice-Presidents: Dr. J. C. Verco, Sir P. Sydney Jones, Dr. F. C. Batchelor, Hon. G. H. Butler, Professor E. C. Stirling, C.M.G., Professor H. B. Allen, Surgeon-General W. D. C. Williams, C.B., Fleet-Surgeon V. Gunson Thorpe, Fleet-Surgeon F. Falconer Hall. The executive committee is composed as follows: President, Past President, General Secretary, Associate Secretary, Treasurer, Dr. G. H. Abbott, Dr. W. G. Armstrong, Dr. Richard Arthur, Dr. Fourness Barrington, Dr. H. G. Chapman, Dr. C. B. Clubbe, Dr. W. H. Crago, Dr. Gordon Craig, Dr. J. A. Dick, Dr. T. Fiaschi, Dr. J. Foreman, Dr. J. Macdonald Gill, Dr. Sinclair Gillies, Sir J. Graham, Dr. H. C. Hinder, Dr. A. Jarvie Hood, Dr. J. L. T. Isbister, Dr. C. H. E. Lawes, Dr. H. L. Maitland, Dr. Odillo Maher, Dr. A. E. Mills, Dr. W. McMurray, Hon. Dr. J. B. Nash, Dr. Russell Nolan, Dr. R. Paton, Dr. Clarence Read, Dr. G. E. Rennie, Dr. Reuter E. Roth, Dr. Eric Sinclair, Dr. R. Scot Skirving, Professor Anderson Stuart, Dr. Ashburton Thompson, Dr. R. H. Todd, Professor Welsh, Professor Wilson, Dr. P. M. Wood, and Dr. Ralph Worrall. Various Sections of Congress:—1. Section of Medicine: President, Dr. W. T. Hayward (Adelaide). 2. Section of Surgery: President, Dr. G. A. Syme (Melbourne). 3. Section of Obstetrics and Gynæcology: President, Dr. G. Rothwell Adam (Melbourne). 4. Section of Anatomy, Physiology, and Pharmacology: President, Dr. E. H. Embley (Melbourne). 5. Section of Pathology, Bacteriology, and Tropical Medicine: President, Dr. Wilton W. Love (Brisbane). 6. Section of Public Health and State Medicine: President, Mr. James W. Hope (Fremantle). 7. Section of Ophthalmology: President, Dr. J. W. Barrett (Melbourne). 8. Section of Psychological Medicine and Neurology: President, Mr. W. Beattie Smith (Melbourne). 9. Section of Diseases of Children: President, Dr. A. Jeffreys Wood (Melbourne). 10. Section of Naval and Military Medicine and Surgery: President: Colonel C. S. Ryan (Melbourne). 11. Section of Dermatology, Radiology, and Medical Electricity: Presidents, Mr. H. F. Lawrence (Melbourne) and Dr. F. J. Clendinnen. 12. Section of Laryngology, Rhinology, and Otology: President, Dr. W. L. Robertson (Brisbane). The State Secretaries of Congress are Dr. Arthur Jeffreys Wood, 19, Collins-street, Melbourne; Dr. Wilton W. Love, Wickham-terrace, Brisbane; Dr. John B. Gunson, North-terrace, Adelaide; Dr. Gregory Sprott, Macquairie-street, Hobart; Dr. A. J. H. Saw, Perth, West Australia; Mr. Stanley Batchelor, Dunedin, N.Z.; and Dr. W. E. Herbert, Boulcott-street, Wellington, N.Z.

Obituary.

JOHN ANDERSON, C.I.E., M.D. ST. AND., F.R.C.P. LOND.

WE briefly announced last week the death of Dr. John Anderson, late of Harley-street, which event took place on Oct. 10th at 33, St. Charles-square, North Kensington, where he had been residing recently. The sudden occurrence of a severe hemiplegic attack in March last from the first could only have one ending, but, some two months before that ending mercifully came, death in an unexpected and rapid form removed his wife. The whole tragedy has aroused the painful interest and deep sympathy of the medical profession; this it would have done in any event, but in the case of a man so well known and beloved as the late Dr. Anderson the feeling both inside and outside his own profession has been very widespread.

John Anderson was born in 1840 and received his medical education at the Royal Infirmary, Manchester, where he was clinical clerk and dresser to the late Mr. Watson Beevor, one of the senior surgeons, a man well known in those days in Lancashire as a brilliant surgeon and operator. It was probably then that Anderson first acquired the facility as a deft manipulator which he always retained and which made him at one time a very neat and dexterous surgeon. At the Manchester Infirmary he made the acquaintance of Dr. (afterwards Sir) William Roberts, the lecturer on medicine at that school, and this subsequently ripened into a firm friendship during the time that Sir William Roberts and Anderson were both residing in London before the former's death. In 1861 and 1862 Anderson obtained what were the usual qualifications of that time, the M.R.C.S. Eng. and L.S.A. Lond., and was appointed successively house surgeon and house physician at the Manchester Royal Infirmary. Entering the Army Medical Service in 1864 he served for many years in India in the Royal Artillery and was in the "Chestnut Troop of Horse Artillery" until the regimental system was abolished. Throughout his career in India, and, indeed, up to the time of his last and fatal illness, Anderson enjoyed perfect health, and his courage and activity, mental and physical, were due to this fact and to his optimistic nature. These qualities fitted him for the ofttimes trying duties and vicissitudes of Indian army life, and he was indefatigable in rendering medical aid in the presence of epidemic disease. On his return home he served in Edinburgh and at Camberley in connexion with the Royal Military College. Whilst at the former station he availed himself, as far as practicable, of the great advantages of Edinburgh University, studied hard there, and went through a course of practical anatomy. He returned to India in a dignified and responsible capacity, for he was specially selected by the late Marquis of Ripon for his personal staff. He accompanied Lord Ripon to India and returned with him to England at the end of his Viceroyalty, having been previously made a Companion of the Indian Empire. He was greatly esteemed by the Viceroy and his staff, and his medical opinion was much sought after by patients of every class.



JOHN ANDERSON, M.D. ST. ANDREWS, F.R.C.P. LOND., C.I.E.

He retired from the Army in 1885, with the rank of Brigade-Surgeon, and began practice in London, becoming physician to the *Dreadnought* Hospital for Seamen and to King Edward's Hospital for Officers, and was for many years member of the Appeal Board at the War Office. He was also appointed lecturer on tropical diseases at St. Mary's Hospital. When he decided to commence practice in London he graduated in medicine at the University of St. Andrews and took the Membership of the Royal College of Physicians of London, of which corporation he was later made a Fellow. At first he practised in Gloucester-place, but soon afterwards moved to 9, Harley-street. His great and varied experience in India made him from the beginning a recognised authority on tropical disease. But it would be a great mistake to regard his practice as having been limited to that direction, for it was really of a very varied character. He was found by those who called him in to be so helpful in diagnosis and so resourceful in his suggestions for treatment that he rapidly passed from the position of a specialist in tropical medicine to that of a general consultant physician. He was transparently loyal in all his dealings, and possessed the happy knack of inspiring confidence, so that without a trace of insincerity he would turn even chance acquaintances into personal friends. It must have been the recognition of his sterling qualities of character as well as of his medical knowledge that led so many of the medical leaders of the day to seek his advice and help when they themselves or those near to them were sick, and all of them honoured him with their friendship. He was essentially a working and practical man, and made but few contributions to medical literature, but his communications to our columns were sound clinical observations.

"About 48 hours prior to the date (in March last) of his fatal illness," one of the oldest and most intimate of his many friends writes to us: "Anderson seemed at his best. He made a long visit to my house, and I had never seen him in better form, health, and spirits than on that occasion. His talk was on literary and scientific as well as on professional and political topics, and he expressed himself in a genial and outspoken way and with a clearness that was delightful to listen to at the time, and calculated, like all close intercourse with him, to leave a fragrant recollection in the consciousness of his listener. For there was nothing mean in thought and deed about him. What he gave he gave with an open palm, and

> 'With liberal hand and bounteous heart
> Shared all his little fortune could impart.'"

The impression of geniality, generosity, and ability conveyed by the words which we have quoted sum up the man, and show why his loss has been so widely felt.

He was attacked early in March last with a grave form of paralysis (right hemiplegia and aphasia) from which he never recovered, and died, as already said, on the night of Oct. 10th. He had throughout his illness the unremitting attention of his old friend and fellow student at the Royal Infirmary, Manchester, Dr. Alfred Clarke, late of the Royal Military College, Sandhurst, and that of Sir William Allchin, Surgeon-General Marston, and others. Dr. Anderson married, in 1877, Miss Jessie Usher Dunlop, who died very suddenly on August 10th last. He leaves four children, to whom we offer our deep sympathy.

PROFESSOR ERNST VON LEYDEN.

THE whole medical profession has to mourn the death of Dr. Ernst von Leyden, formerly professor of clinical medicine and director of the First Medical Clinic of the University of Berlin.

Professor von Leyden was born in 1832 at Danzic, his father being a high official in the Government service, and at the early age of 17 years he became a medical student in the Army Medical College at Berlin, where he took the degree of M.D., and passed the State examination in 1853. He then served as a military surgeon in the army till, in 1862, he was commissioned to take one of the assistantships at the Charité Hospital reserved to army medical officers. He in this way became an assistant to the celebrated physician, the late Professor Traube, at that time professor of clinical medicine, and the first man in Berlin to introduce modern experimental methods in clinical teaching. Professor Traube soon recognised the talents of his assistant and employed him in the most difficult clinical work. On his instigation Dr. von Leyden applied himself especially to diseases of the spinal cord. The results of his studies were his works on "The Degeneration of the Posterior Tracts of the Spinal Cord" and the "Clinic of Diseases of the Spinal Cord," which brought him much celebrity as a teacher and writer. He accordingly left the army, being called as early as 1865 to take the chair of Clinical Medicine at the University of Königsberg. He lived there till 1872, when he left Königsberg for the newly founded University of Strasburg. In 1876 he became the successor of his master, the late Professor Traube, as professor of medicine in Berlin, and held that appointment till 1907, when he resigned because of his advanced age. After his first work on spinal diseases he wrote a great many others—on bulbar paralysis, on aphasia, and on cerebral pressure. His work, however, was not confined to the diseases of the nervous system, but extended to many other departments of medicine. He found in the sputum crystals named after the celebrated French *savant*, Professor Charcot; he described subdiaphragmatic abscesses, and showed that endocarditis might be caused by Neisser's gonococcus and Fränkel's pneumococcus. He was not only a medical writer and an original observer, but a great physician, and in his clinical lectures he always laid stress on the therapeutical side of medicine. This may appear now rather common-place, but was not so at a time when the great majority of clinical teachers cultivated exact diagnosis but neglected the details of treatment.

As a physician Professor von Leyden was of European renown, and patients of every country were found in his consulting-room. Russians went in great number to consult him, and he was often called to Russia to see patients who were unable to travel. The number of his Russian patients included the late Emperor Alexander III., but he had a large *clientèle* among other reigning families also, and he was one of the physicians in attendance on the late Emperor Frederick during his last illness. At the same time he was not neglectful of the sick poor, and a great deal of his work during the later period of his life was devoted to the care of indigent tuberculous patients. It was especially by his endeavours that the sanatorium movement in Germany has been so successful and that thousands and thousands of indigent patients are now received all the year round in these institutions. He took a prominent part in schemes for the prevention of tuberculosis, and was one of the presidents of the Central Committee on Tuberculosis. At a very advanced age he began systematic study of the prevention of cancer which he believed to be of an infectious nature. A central committee having this for its object was founded and presided over by him, and dispensaries for cancerous patients were established. When he resigned his post as professor of medicine in 1907 he continued to be at the head of a cancer ward, especially created for him, in the Charité Hospital.

His faculty of being up to date, even at an age when other men have some difficulty in following new ways, was one of the principal features of his character, and therefore he became fully aware of the importance of physical and dietetic treatment. He recommended this treatment in his clinical lectures, and edited, together with his former assistant, Professor Goldscheider, the *Zeitschrift für Physicalisch-Diätetische Therapie*. A great work, "Die Deutsche Klinik am Beginn des 20. Jahrhunderts," edited by him and Dr. Klemperer, was a description of modern views and methods of clinical medicine. He was a constant opponent of excessive specialism in medicine, and when he believed that in the Berlin Medical Society clinical medicine was put somewhat in the background by the different special branches he did not hesitate to resign his membership and to found in Berlin a new society for internal medicine, of which he was the president until his death. He also was the founder, and on various occasions the chairman, of the Congress für Innere Medicin.

During his long career many and high honours were conferred on him. On the occasion of his seventieth birthday he received titular honours, and a few years ago the rank of Real Privy Councillor, with the title of Excellency, was conferred on him. He continued to be very active until last winter, when he fell on the stairs and sustained a fracture of the neck of the femur from which he did not recover. His death will be greatly deplored, not only because of his attractive personality, but also because he was a good man and a good physician.

CHARLES HANLEN GAMBLE, M.R.C.S. ENG., L.S.A., J.P.,

CONSULTING SURGEON TO THE NORTH DEVON INFIRMARY.

Mr. C. H. Gamble died recently at his residence in Barnstaple. The deceased, who was the oldest member of the medical profession in North Devon, was born in 1825, his father being the late Rev. H. Gamble, vicar of Newport, Barnstaple. He received his medical education at Guy's Hospital and qualified M.R.C.S. Eng. and L.S.A. in 1848. He shortly afterwards commenced practice at Barnstaple, joining his uncle, the late Dr. T. S. Law. Mr. Gamble practised in Barnstaple for about 60 years, and it was only quite recently that he retired from active work. He had been a member of the honorary medical staff of the North Devon Infirmary for more than 50 years. He was a magistrate for the borough and at one time was a member of the town council. Mr. Gamble was one of the first to join the Volunteer movement and was formerly surgeon-major in the North Devon Yeomanry. He took a great interest in everything connected with Barnstaple and was highly respected and esteemed by all the residents of that town. He was a staunch Churchman, and for many years churchwarden at Holy Trinity Church. Mr. Gamble celebrated his golden wedding about a year ago. He leaves two children—the Rev. H. R. Gamble, vicar of Holy Trinity, Chelsea, who was formerly mayor of Chelsea, and Mrs. James, wife of a solicitor at Barnstaple. Mr. Gamble will be much missed in North Devon, especially by the poor, to whom he was always a generous friend.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Francesco Laccetti, *privat-docent* of anatomy in the University of Naples.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Registration Bill.

IN the forefront in many things, New Zealand still lags behind with respect to the law governing the registration of medical men. Many attempts have been made to remove the disabilities under which the profession labours, but democratic parliaments are somewhat fearful of what are termed close corporations. The most recent attempt to bring our law into line with that of other countries is in a great measure due to the energy and insistence of Dr. H. E. Gibbs of Wellington. The Bill, which it is hoped will be taken up by the Government, provides for the incorporation of a society to be termed the Society of Registered Medical Practitioners of New Zealand. The affairs of the society are to be managed by a board consisting of (1) one registered medical practitioner for each district to be appointed by the Governor; (2) one registered medical practitioner resident in the district elected by the practitioners in the district; (3) and one practitioner elected by the New Zealand University

Senate. The usual machinery is included for the working of the board, but Section 12, however, seems far from satisfactory. It runs as follows :—

(1) The Board may from time to time make regulations for the purpose of regulating its own procedure, and of generally carrying this Act into effect, but no such regulations shall have any effect until it is *approved* by the Government and gazetted. (2) The Governor may from time to time suspend the operation of any such regulations.

It will be seen from this that in any real conflict the power will lie in the hands of the Government. Sections 14 and 19, which deal with the erasure of offending members' names from the Register, are also far from satisfactory, but I fear that, even incomplete as they are, there will be great opposition when the Bill comes before Parliament. These sections give to the person whose name has been ordered to be removed from the Register power of appeal to the Supreme Court, "and such appeal shall be in the nature of a re-hearing." Thus it will be seen that the powers of the board do not err on the side of being too absolute. The qualifications for registration are: (1) A graduate in medicine or surgery of the New Zealand University; or (2) registered on the Register kept in accordance with the provisions of the Acts regulating the registration of medical practitioners in the United Kingdom; (3) eligible for registration on such last-mentioned Register; or (4) the holder of a foreign diploma approved by the board, granted after a course of not less than five years' study of the subjects pertaining to a medical or surgical degree or licence. Provided that no university, college, or other body in any country other than the United Kingdom shall be recognised by the said board for the purposes of this Act unless it appears to the board that the graduates in medicine or surgery of the University of New Zealand are by virtue of such graduation, and without further examination, entitled to practise medicine and surgery in such country, either on registration therein or otherwise. 5. One from whom no testimonial, diploma, licence, nor certificate has been withdrawn by the college, university, or other body granting it on account of the holder having been convicted of infamous conduct in a professional respect or of a felony or misdemeanour. 6. A person of good fame and character.

Children's Hospital, Wellington.

For some time past the need for a better hospital for children in the capital city has been obvious. In response to an appeal by the Mayor the sum of £6000 was collected in about ten days. Most valuable help was rendered by Mr. Ward and Miss Grace Palotta, members of a theatrical company which happened to be playing in Wellington during the collection week. With the subsidy of 24*s.* per pound from the Government there is every hope that ere long a suitable hospital will be established.

Contagious Diseases Act.

At the invitation of the Attorney-General, the medical associations have held several discussions on the question of whether there should be any alteration of the law relating to contagious disease. There is at present on our statute-book a Contagious Diseases Act which gives power to local authorities to bring into force the provisions of the Act. For a great number of years the Act has been practically a dead-letter because no municipality has availed itself of the provisions of the Act. Every year certain associations of women petition for a repeal of the statute. Hitherto the Government has simply "received" the petition, but this session it has been moved to suggest that the Act should be repealed. Before taking action, however, the Attorney-General has requested from the profession a statement as to the amount of syphilis in the Dominion, and what measures it considers necessary. There would appear to be no very definite data available, and the counsels offered are truly various. The general opinion seems to favour the recommendation of the late chief health officer that syphilis ought to be included amongst the list of notifiable diseases. If this were done, with a very slight amendment of the Public Health Act, complete control of recognised brothels could be accomplished, syphilis and gonorrhœa would be brought into line with the other infectious diseases, and the same measures could be employed to prevent their spread. A great deal would depend upon the wisdom exercised by the officials in what action they took upon notification. Desirable as it is, however, that something should be done to check the evil consequences of such diseases, there will, I fear, be much opposition offered when the suggestion comes up for decision in the House. The reason for the present discussion was the asked-for removal of the only Act on the statute-book dealing with contagious diseases, and it is unlikely that the petitioners will be satisfied with anything less than its removal.

Sept. 5th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the quarterly meeting of the Council held on Oct. 13th the undermentioned diplomas were conferred upon the following gentlemen, who have now complied with the by-laws :—

M.R.C.S.—Walter Egbert Fox, Guy's Hospital; William Macewen, M.B., Ch.B. Glasg., Glasgow University and Charing Cross Hospital; Edward Vernon Whitby, M.B., Ch.B. Birmingham, Birmingham University.

L.D.S.—Harold Todd Reeve, Guy's Hospital; and Albert John Schaefer, Guy's Hospital.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; and C., Chemistry) :—

Robert Aitken (B., P.), George Kirkwood Allan (B., P.), John Anderson (Z., P., C.), Andrew Duffield Blakely (Z.), John Bradford (B., P.), Maurice Smith Bryce (B., Z., P., C.), John Cameron (B., Z., C.), John Campbell (Z.), John Munro Campbell (B., P.), Thomas Watson Carstairs (B.), Alfred Mackenzie Clark (B., P.), Robert Clark, M.A. (B., Z., P., C.), Andrew Climie (B., P.), William Combe (B., P.), James Paterson Crawford (B., P., C.), Henry Paterson Crow (B., P.), Fritz Vivian Daeblitz (Z., P.), Michael Devers (B.), Alexander Hogg Donaldson (B., P.), Thomas Ingram Dun (Z.), Dugald Ferguson (B., P., C.), Thomas Ferguson (Z., C.), Harry Taylor Findlay (B., P.), James Jackson Finlay (B., P.), George Fleming (B., Z., P., C.), Robert Forbes (B., P.), Ian Maclean Frazer (Z., C.), Robert Frew, B.Sc. (B., P.), Walter Weir Galbraith (Z.), David Gould Gardiner (B., P.), Leonard Woodburn Gemmell (Z., P.), John Albert Frank Gibson (B., C.), Robert Stuart Gibson (B., P.), William Gibson (B., P., C.), John Aitken Gilfillan (B., P.), Peter Gordon (B., P.), Ronald Thomson Grant (B., P.), Alexander Hislop Hall (B , P.), David Cochrane Hanson (B., C.), Joseph Welsh Park Harkness, M.A. (B.), Fergus Leslie Henderson (B., P.), Rollo Isbister (B., P., C.), Alastair Caulfield Jebb (B., P.), Douglas Reid King (Z., P., C.), George Kirkhope (B., P.), William Fulton Kivlichan, M.A. (C.), Robert Kyle (B., P.), Hugh Brown Lawrie (B., P.), Robert Lindsay (B., P.), Alfred Thomas Logan (B., P.), George M'Callum (B., P.), Joseph M'Culloch (B., C.), Archibald Munn M'Cutcheon (B., P.), Robert William MacDonald (B., Z.), Donald John Macdougall (B., Z., C.), Donald Kerr MacDougall (B., P.), Gerald James M'Gorty (B., P.), Donald M'Intyre (B., P.), David Mackie (P.), James Graeme M'Kinna (B., P.), Joseph Allan Maclean (B., C.), Malcolm Bonar Macleod (B., P.), David M'Neill (B., P.), James Kennedy Manson (Z., C.), Walter John May (C.), Thomas Duff Miller (B., P.), James William Moffatt (B., P.), Percival John Moir (B., Z., C.), Laurence Sebastian Morgan (B., Z., P., C.), Hugh Adam Munro (P.), Thomas Fraser Noble (Z.), William O'Brien (Z., C.), John Roberts Pate (B., P.), James Paterson (B., P.), Andrew Picken (B., P.), John M'Lean Pinkerton, B.Sc. (B., Z.), John Stuart Prentice (C.), Hugh Quigley (B., Z., C.), Angus M'Innes Ramsay (Z.), Frederick Powlett Rankin (B.), Adam Rankine (B.), Thomas Forbes Brown Reid (B., Z., P., C.), David Bell Robertson (Z., C.), George William Ronaldson (P.), Robert Rowan (B., P.), Archibald M'Kerrow Russell (B., P.), William Jack Scade (B., P.), Seymour Cochrane Shanks (B., P.), William Frederick Shanks (B., Z.), Thomas Robertson Sinclair (B., Z., P.), John Smith, M.A. (B., Z.), Norman M'Gaan Smith (B., P.), John Banks Steven (B., P.), John Fraser Steven, M.A. (B., Z.), Henry Stewart, M.A. (B., Z.), Robert Sutherland Strachan (P., B.), Robert Taylor (B., P.), Donald Fraser Sage Thomson (B.), Robert Noel Thomson (B., P., C.), James Vallance (B., P.), James Walker (C.), William Semple Wallace (B., Z.), William James Cunningham Watt (Z.), John Allan White (Z.), Robert Horatio Williamson (Z.), Alexander Sweet Wilson (P.), James Gordon Wilson (P.), Robert James Wilson (B., P.), Thomas M'Skimming Wilson (Z.), John Wylie (B., P.), Alexander Young (C.), and Gavin Young (Z., C.).

Women.—Dagmar Florence Curjel (B., P.), Margaret O'Rourke Gallagher (B.), Ethel Winifred Gomperts (B., P.), Florence Scott Kirk (B., P.), Jessie Gordon M'Laren (B., P.), Janey Lamond Munro (B., P.), Helen Young Murdoch (B., P.), Mary Isabel Sinclair (C.), Grace Birrell Whish (B., P.), and Mary Ferguson Wood (Z.).

The following have passed the Second Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., Anatomy; and P., Physiology; and M., Materia Medica and Therapeutics) :—

William Larmour Anderson (A., M.), James Angus (M.), Simon Harry Bloom (A.), William Brown (A.), Alexander Grahame-Buchanan (A., M.), James Wilson Burton (A.), Norman Cameron (A., M.), George Wilson Clark (A.), Robert Craig, M.A. (M.), Daniel Augustine Cush (A., M.), Alexander Hugh Davidson (A.), James Henry Dible (M.), Philip Figdor (A.), John Maitland Forsyth (A., M.), William

Fotheringham (M.), James Fraser (A.), Adolph Robert Hanns Geyer (M.), Leopold Glushak (A., M.), Cecil William Fletcher Greenhill (A.), John Ferguson Hutton, M.A. (A.), Thomas Pollock Inglis (A., M.), Charles Joseph Hamilton Kirk (A.), John Finlayson Lang M.A. (A., P., M.), William Joseph Brown Lavery (P.), Frank Whitwell Kinnear Lawrie (A., P., M.), Robert Aim Lennie (A., P., M.), Carel Johannes van Lingen (A., P., M.), John Aloysius M'Connochie (M.), James Ronald M'Curdie (A.), John Henry Magoveny (A., M.), William Montgomery (A.), Kenneth Duncan Murchison (A., M.), Andrew Neilson (A., P.), John Boyd Orr, M.A., B.Sc. (M.), Andrew Peden (A., M.), James Purdie (A., M.), James Francis Quigley (Lambhill) (A., P.), David William Reid (M.). John Ritchie Richmond Ritchie (M.), Alfred Leopold Robertson (M.), James Gordon M'Gregor Robertson (A.), James Hinton Robertson (M.), Frank Shearar (A.), John Finlayson M'Gill Sloan (A.), Hendrik Cornelius van der Wat Smit (A., P., M.), James Anstruther Smith (A.), John Kenneth Smith (A., P., M.), George Taylor (A., P.), William Taylor (M.), Angus Walker (M.), John Cuthbertson Walker (P., M.), Thomas Walmsley (M.), Frederick John Whitelaw (P., M.), Archibald Wilson (A.), and William Ferguson Wood (A., M.).

Women.—Janet Rankine Anderson (P., M.), Jane Malcolm Davidson, (M.), Lillias Beverley Hardie (A.), Jane Kerry M'Elroy Hunter (M.), Mary Anne Kirk (P.), Maggie Logan Kirkwood (M.), Margaret Helen M'Killop (A., P., M.), Petrina Stewart (A., M.), and Janet Morris Walker (P., M.).

The following have passed the Third Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (P., Pathology; and M., Medical Jurisprudence and Public Health):—

Mark James Aitken (P., M.), James Browning Alexander (P., M.), John Campbell Hill Allan (P.), Alexander John Archibald (P., M.), William Egon Halman Beard (M.), John Bower (P.), Charles Brash (P.), Angus Dugald Buchanan (P.), William Murdoch Buchanan (P., M.), George Cochrane, M.A. (P.), James Alphonsus Joseph Conway (P., M.), James Findlay, M.A. (M.), Robert Findlay (P., M.), David Thomas Crichton Frew (P., M.), John Joseph Gibb (M.), Joseph Graham (M.), Charles Hope Haddow (M.), Andrew Smith Hannay (M.), Daniel Christopher Hayes (P., M.), Alexander Gibson Henderson (M.), Andrew Gray Holms (P., M.), William Hunter Howat (P., M.), James Johnstone (M.), Felix Arthur Kerr (P., M.), Thomas Joseph Kirk (M.), Alexander Kirkhope (M.), Murdoch Hugh MacLeod (M.), Stephen Anderson MacPhee (P.), George Hanson M'Robert (P.), Stuart Spence Meighan, B.Sc. (M.), John Mitchell (P., M.), Michael John Murray (P.), Archibald Naismith (P.), James Eric Paterson (P., M.), Alexander Rae (M.), Henry Charles Deans Rankin (P., M.), Hugh Young Riddell (P.), John Livingstone Scott (M.), William Logan Scott (M.), James Smith (P., M.), Malcolm Sommerville (P.), Lawrence Tweedie Stewart (M.), Thomas Louis Grenet Stewart (P., M.), William Tudhope (M.), Alexander Guthrie Semple Wallace (P.), Tom Waterhouse (M.), Hugh Ferguson Watson, L.R.C.P. (M.), Thomas Whitelaw (P.), Douglas Wilson (M.), Hugh Gilmer Wilson (P.), and Walter Percy Yates (P.).

Women.—Barbara Macgregor (P., M.), Ellen Brown Orr (P., M.), Lucy MacBean Ross (P., M.), Christina Hamilton Shearer (P., M.), and Isabel Jane Stark (P., M.).

The following candidates passed with distinction in the subjects indicated:—

FIRST EXAMINATION.

Botany and Physics.—Archibald Munn M'Cutcheon.
Botany.—Dagmar Florence Curjel and James Graeme M'Kinna.
Zoology.—John Cameron, John M'Lean Pinkerton, B.Sc., and Robert Horatio Williamson.
Physics.—Robert Frew, B.Sc., Robert Stuart Gibson, Ronald Thomson Grant, Robert Lindsay, and Andrew Picken.
Chemistry.—James Kennedy Manson and Gavin Young.

SECOND EXAMINATION.

Materia Medica and Therapeutics.—James Henry Dible, James Hinton Robertson, and Thomas Walmsley.

THIRD EXAMINATION.

Pathology, Medical Jurisprudence, and Public Health.—James Eric Paterson.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on Oct. 12th, Dr. G. F. Blandford, the President, being in the chair. Fourteen directors were present. The audited accounts of the half-year ending June 30th were read and passed. By them it was seen that the income derived from investments during that period amounted to £1497 18*s.* 6*d.*, £245 14*s.* had been received in ordinary subscriptions and £46 4*s.* in life subscriptions. £1310 10*s.* had been distributed amongst the annuitants of the charity. The sum of £534 was voted to be paid in December as a Christmas present, each widow to receive £10, each orphan £3, and each orphan of the Copeland Fund £5. Two medical men were elected members of the society. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. Relief is only granted to the widows and orphans of deceased members; letters are constantly being received from widows of medical men asking for assistance, but this has to be refused as their husbands had not been members of the society. Full particulars and application forms for membership may be obtained from the Secretary at the offices of the Society, 11, Chandos-street, Cavendish-square, W.

KING'S COLLEGE, LONDON: SPECIAL PHYSIOLOGY LECTURES.—A course of four lectures, with experiments, on Tissue Respiration will be delivered in the Physiological Laboratory by Mr. Joseph Barcroft on the following Mondays, at 4.30 P.M.: Oct. 31st, Nov. 14th and 21st, and Dec. 5th. The course is free to students and members of King's College, to internal students of the University of London, to all medical students in London, and to medical practitioners on presentation of visiting cards.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—On Nov. 3rd Professor Osler will deliver an address entitled "The Hospital Unit in University Work" in the Connaught Hall (Y.M.C.A. Buildings), Newcastle, at 4.30 P.M., and will be the guest of the society at a dinner to be held in the King's Hall, Armstrong College, at 7.15 P.M. on the same evening. All members of the medical profession in the north of England are most cordially invited to be present at the address and dinner, for which tickets (price 10*s.* 6*d.*) can be obtained from the secretaries, Dr. William Hume and Mr. R. J. Willan, 25, Ellison-place, Newcastle-on-Tyne.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall, and Cox will publish on Tuesday next, Oct. 25th, a book on "Accidents in their Medico-Legal Aspect," which they have had in preparation during the last two years. The work is divided into three sections—legal, medical, and a case guide—and the index covers all three parts. The medical part of the book has been written by over 30 medical men who are, or have been, teachers at the great schools of medicine. The case guide is a short epitome of nearly every case referred to in the legal section, with a number of other cases of personal injury. This royal octavo volume of about 1300 pages is published at 30*s.* net, and should be of great use to both the medical and the legal profession.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of this society was held on Oct. 14th, when the President, Dr. W. G. Willoughby, delivered an address on the Duties of a Medical Officer of Health. After referring to the more or less definite duties prescribed for medical officers of health by orders of the Local Government Board, he pointed out that these apparently limited their work to the prevention of disease. The boundary-line between prevention and treatment was so very indefinite—such, for example, as the sanatorium treatment of consumption and the use of antitoxin—that certain treatment had for some time been included within the scope of their duties. Though no one could rationally object to the two instances given, it was a matter for considerable doubt and debate as to how far a medical officer of health should go in the actual medical and surgical treatment being introduced in the form of school clinics. He dealt at some length with the important part played in public health by the home life of the people and urged that medical officers of health should find time to study the houses of the poor in their districts. He did not altogether agree with the statement contained in the Minority Report of the Poor-law Commission that four-fifths of the work of the medical officer of health was wrapped up in the casual labourer and his home. Poverty, overcrowding, hopelessness, ignorance, unemployment, consumption, mental defectiveness, crime, and alcoholic excess were often so closely intermingled that which was cause and which effect it was difficult to decide. The insanitary house was the constant accompaniment of these conditions, and from them came the bulk of the dirty conditions and neglect which led to personal ill-health. He then referred to a fact taken from a small experience that mentally defective children were found to be specially connected in undue proportion with dirty and unsatisfactory houses. The causes of this special connexion were sometimes difficult to determine, but often mentally defective children had mentally defective parents, and the neglect of the home and children might be due to weak-mindedness rather than to viciousness or intentional neglect. It was unfortunate that efforts during school life to improve the intelligence of a feeble-minded child often resulted in bringing it to a state when it could merge, though imperfectly intellectually developed, into the marriage market with disastrous results to the future generation. In Dr. Willoughby's opinion, the sooner the Government adopted these feeble-minded people and directed their careers the better it would be for the public health of the country. The annual dinner of the society was held on the same evening at

the Waldorf Hotel. The President occupied the chair, and the company included Sir Dyce and Lady Duckworth, Mrs. W. G. Willoughby, Rev. Dr. and Mrs. J. M. Willoughby, Sir Lauder Brunton, Mr. F. Hollins, Sir Shirley and Lady Murphy, Mr. and Mrs. H. T. Butlin, Mrs. B. Broadbent, the Mayor of Battersea, Dr. J. Priestley, and Mr. W. A. Lawton.

READING PATHOLOGICAL SOCIETY.—The annual meeting and dinner of this society took place on Thursday, Oct. 20th, when an annual oration was given by Sir Lauder Brunton, Bart., who chose as his subject, "Blood Pressure from a Clinical Point of View."

THE Master and Wardens of the Society of Apothecaries of London attended Divine service on St. Luke's Day, Oct. 18th, at St. Anne's-by-the-Wardrobe, E.C., and dined together in their hall in the evening, the occasion being the induction of the new Master, Mr. A. T. Norton, C.B. The Court of Examiners and many of the deans of the London medical schools were guests, and heard a very practical speech from Mr. Norton.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—On Oct. 5th Mr. James Taylor, M.D., C.M. Aberd., J.P. for Banffshire, was presented by his patients and friends in the town of Keith and surrounding districts with a motor car as a mark of their respect and esteem after 25 years' active practice. Provost Cameron, who made the presentation, said, generally speaking, they owed much to the profession to which Dr. Taylor belonged, for to its members were mainly due the great advancement in sanitation and improved conditions affecting the public health. Twenty-five years had passed since first Dr. Taylor commenced practice in Keith after a distinguished university career, and during that time he had spared neither his time nor his health, and had gained the confidence of an ever-increasing *clientèle*, not only as a trusted and skilful physician, but also as a counsellor and sanitarian. Four handsome silver candlesticks, together with a hall gong, bearing the following inscription, were presented to Mrs. Taylor: "This gong, together with four silver candlesticks, was gifted to Mrs. Taylor as a memento of the presentation to Dr. Taylor of a motor-car on the attainment of his semi-jubilee as a medical practitioner in Keith and district. August, 1910."—Mr. Richard Brayn, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., medical superintendent of Broadmoor Criminal Lunatic Asylum, was presented by the staff, on Oct. 14th, with a silver rose-bowl and an album on the occasion of his retirement.

LONDON SCHOOL OF TROPICAL MEDICINE.—The annual school dinner was held at the Savoy Hotel on Oct. 14th, Mr. James Cantlie being in the chair. After the loyal toasts had been given, Mr. W. H. Lever (chairman of the Liverpool School of Tropical Medicine) proposed the toast of "The School." He referred to the need of money for carrying on the important imperial and economic work of research in tropical medicine and the desirability of making known this need. The Schools of Tropical Medicine both in London and Liverpool, between whom the most cordial relations existed, were engaged in breaking down the barrier which blocked the utilisation of the great resources of the tropics, and deserved from Government more help than they were given, if only in return for the half-million pounds annually which tropical medical officers saved the nation in the lives of men of the army and navy. Mr. James Cantlie responded, extending to Mr. Lever, as representing the Liverpool School, the same feelings of cordiality which he had expressed towards them. The toast of "The Orator of the Day" was proposed by Lord Sheffield and responded to by Dr. Henry Miers, who referred to the need for closer coöperation between the University of London and its schools, which might be supplied by providing the University with a building suitable to its dignity and requirements. Mr. Percival Nairne proposed "The Guests," a toast which was responded to by Sir Havelock Charles. The health of the chairman was proposed by his friend, Professor W. J. Simpson, and in reply Mr. Cantlie made a speech of characteristic humour which was so well received that he concluded with the remark "London folk are no ill to please." Amongst those present were Sir West Ridgeway, Mr. E. W. Blessig, Professor W. R. Smith, Sir William Treacher, Surgeon-General J. E. Godfrey, Dr. F. M. Sandwith, Sir Francis Lovell, Mr. H. J. Read, and many officers of the Army Medical and Indian and Colonial Services.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students will be held on Saturday, Nov. 26th, at the Hôtel Métropole (Whitehall Rooms), under the presidency of Mr. H. Lloyd Williams. Gentlemen either now or formerly connected with the hospital or medical school who may, through inadvertence, not have received special notice and who desire to be present are requested to communicate with the Dean at the Royal Dental Hospital, 32, Leicester-square, London.

DONATIONS AND BEQUESTS.—By the will of the Rev. Henry Thornhill Morgan, vicar of St. Peter in Eastgate with St. Margaret, Lincoln, the testator bequeathed £500 to the East Derbyshire Hospital, Chesterfield, and £100 to the Royal Berkshire County Hospital, Reading.—The late Mr. William Hall of London, N., among other bequests, left £500 to the Lincoln County Hospital.—A gift of £1000 has been made to the funds of the Stratford-upon-Avon Hospital by Mr. W. B. Gibbins, a member of the Society of Friends.—The late Mr. Edward Matyear has left by will £500 to the West London Hospital, and the residue of his estate, amounting to over £60,000, to King Edward's Hospital Fund.

THE COUNTY COUNCIL AND THE MILK-SUPPLY OF LONDON.—During the three months ended Sept. 30th, 1910, 753 samples of milk sent to London from the home, Midland, and Western counties were taken by London County Council inspectors at the principal railway termini. The examination of 641 samples has been completed, with the result that 79, or 12·3 per cent., were found to be tuberculous. Part IV. of the General Powers Act, under which this work is authorised, came into operation on July 1st, 1908, and the total number of samples taken since that date is 4915: 4126 have been examined, and 435, or 10·5 per cent., found to be tuberculous. Of 3152 cows examined on farms during the quarter, 38, or 1·2 per cent., were found to be suffering from tuberculosis of the udder. The percentage since the Act came into operation, based on 23,978 examinations, is 1·8.

WITH the object of drawing the attention of medical men and the public to their obligations under the Notification of Births Act, Dr. C. S. Jaffe and Dr. W. W. Don were summoned, at the instance of the Paddington borough council, before the magistrate at Marylebone police court, for that, having been present at the birth of certain children in the parish, they failed to give notice in writing of the birth to the medical officer of health within 36 hours afterwards. The fathers of two children were also summoned for failing to give notice. Mr. Dennis, for the council, stated that over 60 summonses might have been issued against medical practitioners and fathers, but the council had contented itself with four. The magistrate inquired if there was any objection on the part of the medical profession to give notice of births, and was informed by Dr. R. Dudfield, the medical officer of health of Paddington, that there was an objection because no fees were paid for the service imposed. He added that the Act had had the effect of greatly reducing infantile mortality. The magistrate considered that Dr. Jaffe had not complied with the Act and fined him 5*s.* and 2*s.* 6*d.* costs, pointing out that there was no suggestion against him of unprofessional conduct. The summons against Dr. Don was withdrawn, his defence being that he understood from the midwife in attendance that the father had given notice.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

COLYER, F. C., M.R.C.S., L.D.S., has been appointed a Member of the Board of Examiners in Dental Surgery of the Royal College of Surgeons of England.

COWAN, G., M.D. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Thetford District of the counties of Norfolk and Suffolk.

BOKENSTEIN, KENNETH, M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Assistant Pathologist to the National Hospital for Diseases of the Heart, Soho-square, W.

ELLIS, L. ERASMUS, M.D. Brux., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Clinical Assistant to the X-ray Department and Medical Electrical Department, West London Hospital.

ELLIS, WILLIAM GILMORE, M.D. Brux., M.R.C.S., L.S.A., has been appointed an Official Member of the Legislative Council of the Straits Settlements.

FEILING, ANTHONY, L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer at the British Lying-in Hospital.

FELLS, ARTHUR, M.B., C.M. Edin., has been appointed Assistant Surgeon to the Bristol Eye Dispensary.

HAMPSON, WILLIAM, L.S.A., has been appointed Electro-Therapeutist to St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

HATHERLEY, S. O., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Swinton District of the county of Yorks, West Riding.

KNOX, ROBERT, M.B., C.M., M.D. Edin., M.R.C.S., L.R.C.P. Lond., has been appointed Director of the Electrical and Radio-therapeutic Department at the Cancer Hospital.

PORTEOUS, HAROLD BURNET, M.B., C.M. Edin., has been appointed Assistant Surgeon to the Bristol Eye Dispensary.

SIMPSON, J. B., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Golspie District of the county of Sutherland.

STACK, EDWARD HUGH EDWARDS, M.B., B.C Cantab., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgeon to the Bristol Eye Dispensary.

TAYLOR, WILLIAM PEACH, L.S.A. Lond., has been appointed Assistant Surgeon to the Bristol Eye Dispensary.

THOMPSON, J. E., M.B., Ch.B. Aberd., has been appointed Junior House Surgeon at the Southport Infirmary.

WILSON, HAROLD W., M.S., M.B. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Cancer Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL AND DISPENSARY.—Senior House Surgeon, unmarried. Salary £120 per annum, with apartments, board, and laundry.

BATTERSEA POLYTECHNIC, London, S.W.—Lecturer for Friday evenings on "Meat and Food Inspection."

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £100 per annum, with apartments, board, and attendance.

BRENTWOOD, ESSEX AND COLCHESTER LUNATIC ASYLUM.—Senior Assistant Medical Officer. Salary £300 per annum, with apartments, board, attendance, and washing.

BURNLEY, COUNTY BOROUGH OF.—Assistant Medical Officer of Health. Salary £250 per annum.

BUXTON, DEVONSHIRE HOSPITAL.—Assistant House Surgeon for six months. Salary £70 per annum, with apartments, board, and laundry.

CANCER HOSPITAL, Fulham-road.—Surgeon.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Physician, unmarried. Salary £70 per annum with board, lodging, and washing.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon for six months. Salary £30, with board, residence, and laundry.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Registrars. Also Clinical Assistants.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—House Surgeon, unmarried. Salary £30 per annum.

CHELTENHAM GENERAL HOSPITAL.—Surgeon-in-Charge of Branch Dispensary, unmarried. Salary £80 per annum, with board and lodging. Also House Physician, unmarried. Salary £75 per annum, with board and lodging.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £60 per annum, with board, apartments, and laundry.

CITY DISPENSARY, 29 and 30, College-street, Dowgate-hill, E.C.—Surgeon.

DENBIGH, NORTH WALES COUNTIES ASYLUM.—Medical Superintendent. Salary £500 per annum, with house, &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board and lodging. Also Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging &c.

DOUGLAS, NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 per annum, with board and washing.

EVELINA HOSPITAL FOR SICK CHILDREN Southwark Bridge-road, S.E.—House Physician for six months. Salary £60 per annum, with board, residence, and washing.

FRENCH HOSPITAL, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, unmarried. Salary £50 per annum, with board and laundry.

FULHAM, PARISH OF.—Junior Assistant Medical Officer for six months. Salary at rate of £100 per annum, with board, furnished apartments, and washing.

GLASGOW, UNIVERSITY OF.—Examiner in Physiology, Examiner in Surgery (Systematic and Clinical), and an Examiner in Medicine (Systematic and Clinical).

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—Surgeon.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50, with board, residence, and laundry.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, board, and washing.

LISCARD, WALLASEY DISPENSARY AND VICTORIA CENTRAL HOSPITAL, Cheshire.—House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance, &c.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Pathologist and Bacteriologist. Salary at rate of 50 guineas per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—Honorary Dental Surgeon.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.

PENDLEBURY, MANCHESTER CHILDREN'S HOSPITAL.—Visiting Surgeon. Salary £100 per annum.

PRESTON ROYAL INFIRMARY.—Senior and Junior House Surgeons, unmarried, for six months. Salaries £80 and £60 per annum, with board, residence, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Assistant Physician. Also Assistant Surgeon.

READING, ROYAL BERKSHIRE HOSPITAL.—Second House Surgeon for six months. Salary £60 per annum, with board, lodging, and washing.

ROYAL EYE HOSPITAL, Southwark, S.E.—House Surgeon for six months. Salary £52 10s. per annum, with board and residence.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, London.—Assistant Demonstrator of Bacteriology. Salary £150 per annum.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £60 per annum, with rooms, board, and washing.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House Surgeon. Salary at rate of £50 per annum, with board, residence, and laundry. Also Pathologist and Curator. Salary £50 per annum.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £30 per annum, with board, residence, and laundry.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £32 per annum, with board, residence, and laundry.

THROAT HOSPITAL, Golden-square, W.—Honorary Assistant Surgeon.

WAKEFIELD GENERAL HOSPITAL.—Senior House Surgeon, unmarried. Salary £120 per annum, with board, lodging, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Physician for Diseases of Women. Also Anæsthetist.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

WREXHAM INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Act at Bantry, in the county of Cork; and at Kington, in the county of Hereford.

Births, Marriages, and Deaths.

BIRTHS.

FELL.—On Oct. 17th, at Flan How, Ulverston, the wife of Captain M. H. G. Fell, R.A.M.C., of a daughter.

FITZWILLIAMS.—On Oct. 9th, at Rustington, the wife of Duncan C. L. Fitzwilliams, F.R.C.S., of 64, Brook-street, Grosvenor-square, W., of a daughter.

KIRKNESS.—To Dr. and Mrs. W. Ronald Kirkness, on Oct. 11th, at Chesterfield, London-road, Portsmouth, a son.

VIRET.—On Oct. 9th, at Fernleigh, Horton-lane, Bradford, the wife of B. P. Viret, M.B. Lond., M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

JENKINS—EDWARDS.—On Oct. 12th, at St. Margaret's, Westminster, Herbert Thomas Jenkins, M.R.C.S. Eng., L.R.C.P. Lond., to Margaret Wood Edwards, of Treanna, Anglesey, second daughter of the late Dean Edwards, of Bangor, N. Wales.

SELLS—STOCKMAN.—On Oct. 11th, at St. George's, Bloomsbury, London, Hugh Lancelot Sells, M.B., Ch.B., to Charlotte, eldest daughter of Mrs. Stockman, of Slough.

SMITH—MILLER.—On Oct. 17th, at St. Paul's, Prince's Park, Liverpool, by the Rev. J. O. Coop, M.A., Vicar of St. Catherine's, Abercromby-square, assisted by the Rev. S. S. Horan, M.A., Vicar of St. Paul's, Geo. Francis Rawdon Smith, M.B., Ch.B., eldest son of S. Rawdon Smith, J.P., of Ironbridge, Salop, to Ellen Mary, eldest daughter of the late Alexander Alan Miller, of 59, Peel-street, Liverpool.

WINCH—MORRIS.—On Oct. 12th, at St. James' Church, Kidbrooke, Blackheath, by the Rev. J. W. Morris, M.A., Rector of the parish, assisted by the Rev. F. J. Kendall, Incumbent of St. German's, Blackheath, Stanley Brooke, son of Richard Winch, Morden Grange, Blackheath, to Eleanor Boville, eldest daughter of Clarke Morris, M.R.C.S., J.P., Gordon Lodge, Blackheath.

DEATHS.

HYDE.—On Oct. 12th, at Madeley-road, Ealing, Lieutenant-Colonel Henry Hyde, I.M.S. (retired), aged 70 years.

MACAN.—On Oct. 16th, at Cheam, Surrey, Jameson John Macan, M.A., M.D., aged 65 years.

RINGER.—On Oct. 14th, at Lastingham, Yorkshire, Sydney Ringer, M.D., F.R.S., aged 76 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PHYSICIANS AND CITIES.

In the September number of *St. Bartholomew's Hospital Journal* is an interesting address by Dr. Norman Moore delivered at midsummer to the Abernethian Society. Dr. Moore took for his text sundry episodes in the history of the hospital, pointing out that when anyone now enters through the main gateway he walks over the same ground as that walked over by the Bishop of London who consecrated the hospital chapel in 1123, and by five of the barons mentioned in Magna Charta who were all benefactors of the hospital. So abiding and founded in antiquity are many of the London streets and ways. Inside the hospital were sundry houses which were let to tenants, and one of these who held his house from 1551 to his death in 1575 was John Caius, and his annual rent was £4. He was educated at Gonville Hall in the University of Cambridge and studied medicine in Italy mainly under Vesalius. He was widely read, a good Greek scholar, and later became President of the Royal College of Physicians of London as well as Master of the second foundation of Gonville and Caius. The mention of the College of Physicians naturally reminded Dr. Moore of Linacre, and he in turn of Chambre, who, like Linacre, was a priest as well as physician. Among other posts he was warden of Merton College, and naturally took an interest in Merton's celebrated son John of Gaddesden, whose "Rosa Anglica" he read and annotated, the actual copy being shown to the meeting by Dr. Moore. All these great men, said Dr. Moore, "were imbued with a high sense of public duty and with a regard for every part of learning as well as for their own subject and art."

Chambre, who was Dean of St. Stephen's, Westminster, built the cloisters there, which still remain and are perhaps the latest pre-Reformation ecclesiastical buildings in London. Caius refounded Gonville Hall and built a new quadrangle, also designing and leaving the money for the famous gates of the new Caius College. In another department of art he presented the silver caduceus which is still borne before the President of the Royal College of Physicians of London, and had the statutes of the College bound with silver ornaments. And as Cambridge is adorned by the gifts and genius of one physician, so, too, Oxford has her Radcliffe Library, while in London the British Museum and library owe their inception to Sir Hans Sloane, who, as Dr. Moore mentioned, was a successor of Caius as President of the College of Physicians. While on the subject of physicians and architecture, Dr. Moore might well have added that one of the greatest architects of the land, namely, Wren, had in his early days been a diligent student of medicine and anatomy.

BECHUANALAND PROTECTORATE.

Mr. Barry May, Government Secretary, Mafeking, reporting to the Colonial Office on the affairs of the Bechuanaland Protectorate for the year 1909–10, writes:—"The health of the inhabitants generally was good. There were no outbreaks of serious infectious diseases, while malaria fever, which during the previous year had been so prevalent, reverted in its incidence to normal proportions. The feared appearance of sleeping sickness in N'gamiland, referred to in last year's report, has not been verified. A native was met with by the magistrate in the North-Eastern portion of the district who had been ill, he said, for 18 months, and who showed symptoms pointing to sleeping sickness. In particular, he appeared to experience great difficulty in keeping awake, falling asleep even while in the middle of a conversation. On the other hand, there was no enlargement of the glands of his neck, and a blood smear taken from him was found, on examination by Dr. Moffat at Buluwayo, to contain no signs of trypanosomes. In consequence, however, of the seriousness of the matter, authority was granted for the temporary appointment of a medical officer at Lake N'gami to fully investigate any cases suspected of being sleeping sickness, and to determine if possible, the question as to whether or no the disease actually exists in the country. Dr. W. R. W. James, who has served in Uganda and who has had experience of the disease, was selected for the appointment, and is at the present time on his way to N'gamiland."

FIFTY YEARS OF SCIENCE.

THE well-known journal *Public Opinion* has celebrated its entry into the fiftieth year of publication by the issue on Oct. 7th of a special number which contains many articles of interest, among them being "Fifty Years of Change in British Homes," by Sir Walter Crane; "Fifty Years of History," by Dr. J. Holland Rose, Litt.D., and "Fifty Years of Literature," by Dr. C. T. Wright, LL.D. Sir Oliver Lodge sums up the progress of science during the past half century, in which he, of course, selects the names of Pasteur and Lister to illustrate the advance of medical science. Of Pasteur he says that his discovery of the nature of disease is in the act of revolutionising medicine, while at the same time it is throwing light on the activity of the soil in agriculture, the purification of rivers, the treatment of sewage, and on other problems of great importance. In surgery Lord Lister's discovery has enabled operations to be performed with safety which before were quite impossible, leading to a saving of life which can hardly be imagined.

RES VARIA ET MULTIPLEX.

To the Editor of THE LANCET.

SIR,—As an occasional contributor to your far-flung pages may I be permitted to ask, through their medium, if the users of atoxyl, who have had the misfortune to blind their patients and otherwise meet with disastrous results from its application, have taken care *not to sterilise by ebullition the injection?* It seems, even to me, a very puerile question to ask, seeing that the chemistry of the preparation must be well known, but on no other account can I find an adequate explanation of their bad luck with a drug which to me has been a veritable godsend.

Since 1902, when I first read about the "anilide metaarsenique" in the "Annales of Merck," I have given over 2500 hypodermic injections of a 15 per cent. solution of atoxyl without a mishap. The solution is prepared in the autoclave, as boiling in the open air sets free the "aniline," which is a tissue poison. Of this solution I give 2 c.c., intramuscularly, every second day during a fortnight, and then allow the patient to remain without the medication for a similar period. I use these injections in chronic malaria, chronic skin diseases, and in syphilis, and as a tonic in cases where arsenic is indicated.

As a specific in venereal disease it is not curative, but by alternating its use with that of a *soluble* salt of mercury the writer has had the satisfaction of reducing the mercurial treatment at least by half. "606" is still to be tried in this *ultima Thule*.

In chronic malaria it is well to give, say, two injections of a gramme each of a reliable soluble quinine salt twice a week, and the atoxyl thrice; for example, quinine Monday and Friday, and atoxyl Tuesday, Thursday, and Sunday. Then wait a week, and repeat. This latter, perhaps, may interest more practitioners *outre mer* than those domiciled in England, outside of Albert Dock.

Pardon the intrusion of a very ordinary country doctor far from the centres where science and civilisation have their head-waters, but of one none the less desirous of contributing a droplet to the current, and who begs to subscribe himself, Respectfully yours,

Weissnichtwo, Sept. 18th, 1910. W.

CHRISTMAS HAMPERS AND CLOTHING FOR LITTLE CRIPPLES.

Sir William P. Treloar has again sent us his annual appeal on behalf of the poor crippled children of the metropolis. With the generous assistance of the public Sir William Treloar has for many years provided the poor cripples of London with Christmas hampers, and on a modest estimate the fund brightens the lives of over 30,000 little sufferers at Christmas-tide. His Majesty the King provides 10 guineas a year towards the fund, which is administered on the widest possible basis, and is deserving of generous support. Donations should be sent to Sir William Treloar, 69, Ludgate-hill, London, E.C., and marked "Little Cripples' Christmas Hamper and Clothing Fund."

BOULOU WATER.

WE published last week an analysis of this drinking water, and have been asked to state that the address of the agent is not that which we gave, but is 122, High-street, Kensington, London, W.

BRITISH GOLF COURSES.

Messrs. Duckworth and Co. (3, Henrietta-street, Covent Garden, W.C.) have announced the publication this month of a new work entitled "The Golf Courses of the British Isles." The courses are described by Mr. Bernard Darwin, and there are 64 full-page illustrations by Mr. Harry Rountree. The price is 1 guinea net. Mr. Bernard Darwin is an English international player, who was last year in the semi-final of the Amateur Championship, and is also a well-known writer on golf. We believe that many members of the medical profession may like to know of this book, the golfing holiday being popular among them.

AN EXAMPLE FROM ROME.

THE Syndic, Signor Ernesto Nathan, has issued an "ordinanza" to safeguard the public from a danger of long standing—the consumption of bread and pastry which has been exposed in shop windows, or even at shop doors, to the contamination of flies in the one case and of promiscuous dust in the other. These articles of food must henceforth be exhibited to the buying citizen under glass. Another risk which the "ordinanza" provides against is that of the handling of these articles to test their consistency or freshness—a real risk if one considers the neglect of personal ablution on the part of a public with whom the nail-brush is by no means invariably an appurtenance of the toilet. Henceforth the purchaser will be prevented from fingering the bread and pastry exposed for sale, these articles having now to be exhibited under glass furnished with "cartelli indicatori" (card labels). If, in violation of the "ordinanza," they have been handled by the customer, they are

to be impounded and "esclusi dalla vendita" (removed from sale). Bakers are forbidden to take back or to offer for sale such articles, even after being "grattugiati" (grated), which have been exposed and handled in restaurants or carried back from private houses by the distributers. In restaurants or at railway buffets bread will be put on the table in the necessary quantity, and no more; it will be wrapped in paper; and, if already handled or left behind by preceding guests, it cannot again be offered for consumption. Contravention under any of these heads of the "ordinanza" incurs a severe penalty. The Syndic is already assailed, censoriously, for these opportune measures; but the better-inspired and better-mannered public are on his side, hoping as they do that the worse than untidy practices at which they are aimed will gradually disappear, like that of spitting in public vehicles or on the floors of restaurants—a practice which died hard, till its danger to public health was seen to be not less real than its offence to decency.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Nov. 7th–12th (Cape Town).—Twelfth South African Medical Congress (1910).

In 1911:—

May–October (Dresden).—International Hygiene Exhibition.

June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.

July (Birmingham).—British Medical Association.

August or September (Berlin).—Third International Laryngo-Rhinological Congress.

September (Brussels).—Exhibition of Fractures.

September (Sydney).—Australasian Medical Congress.

Sept. 24th–30th (Rome).—International Congress on Tuberculosis.

,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.

October (Cologne).—International Congress of Criminal Anthropology.

In 1912:—

September (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913 the only fixture so far is in London, where the Seventeenth International Congress of Medicine will take place.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—E. B. Dowsett, W. W. James, J. Howard Mummery): at 8 P.M.

Paper:
Mr. F. J. Bennett: Destruction of Teeth by Milk Germs.

Casual Communication:
Mr. J. F. Colyer: A Myeloid Sarcoma associated with a Septic Oral Condition.

Presidential Address:
Mr. W. B. Bacon.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—A. F. Voelcker, Sir John F. H. Broadbent, Bart.): at 5.30 P.M.

Paper:
Dr. A. M. Gossage and Mr. E. Rock Carling: Multiple Cartilaginous Exostoses.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—J. P. Lockhart Mummery, T. R. Whipham, G. S. Haynes) at 11, Chandos-street, W.: at 4.30 P.M.

Cases, &c.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretary—F. A. de T. Mouillot): at 5.30 P.M.

Presidential Address:
Dr. T. Fred Gardner: Air and Water: Is there Anything New under the Sun?

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Presidential Address:
Dr. Theodore Thomson, C.M.G.: The Enteric Fever Carrier.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Mr. J. Bland-Sutton: The Clinical Aspects of Metastatic Cancer of the Ovary.—Dr. B. Spilsbury: The Pathology of Certain Tumours of the Ovary.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.C.

TUESDAY.—8.15 P.M., Presidential Address: The Influence of Social and Legal Restrictions upon the Practice of Medicine.—Mr. D. Cotes-Preedy: The Law and Experiment.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Mr. Bland-Sutton: Diseases of Elephants' Tusks in Relation to Billiard Balls.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Discussion on the Diagnosis and Treatment of Cystic Tumours of the Breast (opened by Mr. D'Arcy Power, illustrated by Mr. E. H. Shaw).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Syphilis. (Museum Demonstration.)

FRIDAY.—5 P.M., Prof. A. Keith: Specimens illustrating the Various Forms of Imperfect Differentiation of the Sexual Organs and Characters. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. H. Sequeira: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. S. R. Russell: Diagnosis of Disseminated Sclerosis.

TUESDAY.—4 P.M., Dr. C. O. Hawthorne: Clinique (Medical). 5.15 P.M., Dr. L. Guthrie: Tetany and Allied Affections.

WEDNESDAY.—4 P.M, Mr. C. W. Rowntree: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. L. Mummery: Diagnosis in Diseases of the Rectum and Anus.

THURSDAY.—4 P.M., Dr. C. Riviere: Clinique (Medical). 5.15 P.M., Lecture:—Dr. Rozenraad (Homburg): Obesity and Some Changes in Metabolism.

FRIDAY.—4 P.M., Dr. D. Mackenzie: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture II.)

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low; Insects as Carriers of Disease in Tropical Medicine.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: Methods of Extraction of the Teeth, When and How.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Morton: X Ray Examination of the Digestive System.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of the Ear, the Lines on which Treatment should be Based.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. J. Taylor: Treatment of Certain Nervous Diseases.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Injuries to the Eyeball.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 30 P.M., Special Lecture:—Mr. Pendlebury: Some Minor Operations of General Practice.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Tuberculous Peritonitis.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

THURSDAY.—4.30 P.M., Sir Lauder Brunton, Bart.: The Value of Blood-pressure Observation in Medical Practice (Opening Lecture of the Winter Session).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. R. Russell: Paraplegia.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Taylor: Clinical Cases.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Mr. Stuart-Low: Accessory Sinuses.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE CHEST, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Treatment of Eczema in all its Forms.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Habershon: Bronchiectasis.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. G. Wright: Intestinal Obstruction. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (26th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (27th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (29th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An Address
ON
THE CHIEF AIM OF MEDICINE.

Delivered at the Public Health Laboratory, Victoria University of Manchester, on Oct. 7th, 1910,

BY SHERIDAN DELÉPINE, M.B., C.M. EDIN., M.Sc. MANCH.,

PROFESSOR OF PUBLIC HEALTH AND BACTERIOLOGY; DIRECTOR OF THE PUBLIC HEALTH LABORATORY, VICTORIA UNIVERSITY OF MANCHESTER.

GENTLEMEN,—In the early days of civilisation disease was attributed to supernatural agencies, demoniacal or divine, which had, under the influence of certain conjunctions of circumstances, the power to injure materially the body.

MEDICINE IN EARLY TIMES.

My learned colleague, Professor Hogg, whose knowledge of early Babylonian texts allows him to speak with authority, informs me that he has not found evidence in Babylonian records of any preventive methods other than ceremonies intended to ward off spirits. In answer to my inquiries he has kindly given me the following information regarding the practice of medicine in those early days. "People were apt to attach more importance to correct ceremonial in the administration of drugs or in the performance of operations than to the physical effects of the treatment used. To a certain extent, indeed, healing was a priestly duty. The priests, however, may have known a good deal more than the people about the importance of physical treatment, and the word *asu* (physician-healer) may mean a 'skilled' healer, with whom the priest coöperated, rather than a class of priest; the precise relations of the different types of office have not yet been made out fully. According to the subscription to a medical text in the library of the great Assyrian king Ashur-bani-pal, there were three divisions in the healing art: 'healing' (literally, vivifying), 'surgery,' and 'exorcism."[1]

Notwithstanding the fact that the influence of climate, season, &c., is discussed by Hippocrates in his books on "Epidemics," the therapeutic aspect of medicine continued to monopolise almost, if not entirely, the attention of the laity and of the medical profession. Even at the present day the greatest compliment that can be offered to a physician is to call him a healer (*vide* interesting article in the *Manchester Guardian* on the occasion of the centenary of Dr. John Brown).

COMPARISON OF PREVENTIVE AND CURATIVE MEDICINE.

The absorbing interest taken by the medical profession in the treatment of disease by vaccine-therapy was well shown by the length of the discussion which took place before the Royal Society of Medicine during the months of May and June of this year, while only this week the marvellous successes of modern surgery formed the subject of the eloquent inaugural address delivered by Professor Thorburn. I could not help feeling, however, while listening to my distinguished colleague, that much of the success of modern surgery is attributable to the better knowledge of the causes and prevention of infection which has followed the pioneer work of Pasteur and Lister. The growth of this knowledge, which had been exceedingly slow until the beginning of the last century, has during the last 50 years been remarkably rapid and has led to a new conception of the *chief aim of medicine*. The truth of the saying "Prevention is better than cure" has undoubtedly been long accepted, but as regards disease it was only during the second half of the last century that this principle has passed from the sphere of the abstract to that of practice.

In order to realise the consequences of this evolution of ideas it is necessary to compare the objects of curative medicine with those of preventive medicine. Treatment of disease, whether medical or surgical, implies the previous existence of disease, and has therefore to do with living organisms that have already suffered damage and loss of energy which the most successful treatment can only reduce to a minimum but cannot obliterate entirely. Preventive medicine, on the other hand, aims at preventing the occurrence of disease, and, in principle, has to deal on the one hand with living organisms not yet damaged by disease, and, on the other hand, with agents capable of producing disease before the latter have had the opportunity of injuring the former. It is true that, since diseased individuals frequently act as centres of infection, therapeutical methods may find a useful place in the work of prevention, but it is clear that the existence of any case of infection is in itself proof that preventive methods have been neglected or applied unsuccessfully. The object of preventive medicine is therefore to keep the living organisms in that state characterised by a certain *duration of life, absence of pain, capacity for work, and power of reproduction* which is commonly known as *health*.

"It has often been said that the life of man is a perpetual struggle with the forces of nature; that the continual effort is to oppose the tendency to decay and disintegration which is the fate of all organised beings." These words, which I quote from an elementary treatise by F. S. B. François de Chaumont,[2] do not appear to me to indicate a theory upon which a true conception of health could be based. I think that we must look upon health as the *normal reaction* of the *normal organism* to its *average environment and circumstances*. According to this view there is nothing final in our conception of health, for no biologist would be justified in supposing that any living species has reached the limits of its progressive evolution, so long as there is no clear evidence of regressive changes tending towards extinction.

Prevention of disease should not, therefore, be considered as the ultimate aim of hygiene, for it is not unreasonable to hope that as knowledge of functional activities and of the effects of external agencies upon living organisms becomes more complete, the day may come when man will be in a position so to control the conditions of life as to raise the standard of health above the present level. I doubt whether it will be given to any of us to see that day: all we can hope to do is to prepare the way by devoting our energies to the prevention of diseases of which the cause is known, and to the discovery of causes at present unknown. The incompleteness of our knowledge renders this work slow and laborious, but less ungrateful than it must have been to our predecessors.

RESULTS OF PREVENTIVE MEDICINE.

Thanks to the work of Dr. W. Farr and of his successors we have the means of estimating numerically the effects of preventive work upon the health of the inhabitants of this kingdom, and the results obtained during the last 50 years are most encouraging. It is not always easy to interpret correctly detailed statistics, and more particularly those based upon the diagnosis of non-fatal illnesses, because the value of statistics depends entirely upon the accuracy of the observations upon which they are based, but when simple records of deaths are dealt with some confidence may be attached to them. The following tables, which I have taken from the Seventy-first Annual Report of the Registrar-General (1908), show (A) the population of England and Wales for every fifth year from 1861 to 1905, and for the three following years, and (B) the general death-rates for each quinquennium during the same period.

(A) *Population of England and Wales. (Loc. cit. Table I., p. 2.)*

Years.	Population.
1861	20,119,314
1865	21,145,151
1870	22,501,316
1875	24,045,385
1880	25,714,288
1885	27,220,706
1890	28,763,673
1895	30,451,528
1900	32,249,187
1905	34,152,977
1906	34,547,016
1907	34,945,600
1908	35,348,780

(B) *Annual Rate of Mortality per 1000 Persons Living. (Loc. cit. XXXVI.)*

Years.	Rate for persons.
1861–1865	21·4
1866–1870	21·2
1871–1875	20·9
1876–1880	19·8
1881–1885	18·7
1886–1890	18·5
1891–1895	18·5
1896–1900	17·6
1901–1905	16·0
1906	15·4
1907	15·0
1908	14·7

[1] The Babylonian texts give full descriptions of symptoms and prescribe detailed treatment (except in certain cases where they say the physician is to do nothing: "The sick person will die"), but it is likely enough that in those cases also non-physical means were used in addition to the physical.

[2] The Habitation in Relation to Health, 1897.

If we compare roughly the rate of mortality for the quinquennium 1861–1865 with that for the quinquennium 1901–1905 we find that during the five years 1861–1865 out of 20,000,000 persons some 428,000 died yearly, and during the five years 1901–1905 out of the same number of persons some 320,000 died yearly, which indicates that in the second quinquennium out of 20,000,000 persons 108,000 who would have died each year had the 1861–65 rate remained unchanged were during the period 1901–1905 still alive at the end of each of these years. To estimate accurately the value of these figures it would be necessary to enter into many particulars, but it is not necessary to make an absolute estimate of their value to form a general idea of the tendency which they indicate.

Marked as has been the reduction of mortality during these 48 years it is easy to show that further progress is to be expected. An analysis of the chief causes of death during the year 1908 proves that many of these deaths were attributable to infectious diseases or to lesions many of which were due to the previous occurrence of infectious diseases.

Table C, which is based upon the figures published in the Seventy-first Annual Report of the Registrar-General (LXXX.), shows that more than one-half of the deaths which occurred in England and Wales were due to avoidable causes.

C. Proportion of Deaths from the Principal Causes to Total Deaths in England and Wales, 1908. (*Loc. cit. LXXX.*)

	Proportion per 1000 deaths from all causes.	Rate per 1,000,000 living.
Measles	15·4	 230
Influenza	19·4	 290
Whooping-cough	18·9	 280
Diphtheria	10·7	 160
Diarrhœa	35·4	 520
Pneumonia	80·3	 1,180
Tuberculosis, all forms	107·8—287·9	..... 1,580— 4,240
Cancer	62·9— 62·9	..... 920— 920
Diseases of the nervous system	64·0	 940
Diseases of the heart	95·0	 1,410
Diseases of the blood-vessels	60·2	 880
Diseases of the respiratory system	88·7	 1,300
Diseases of the digestive system	54·6	 800
Diseases of the urinary system	32·9—395·4	..... 480— 5,810
Other causes	76·6— 76·6	..... 1,120— 1,120
Premature births and congenital defects	45·7	 670
Atrophy debility	28·7	 420
Violence	38·7—113·1	..... 570— 1,660
Old age	63·2— 63·2	..... 930— 930
All causes	1000—999·1	..... 14,680—14,680

The records given in Table C show how much remains to be done in the field of preventive medicine. Disease will for a long time to come still claim victims who must look to the skilled physician and surgeon for help. The therapeutical art with all its anxieties and triumphs, its strong appeal to human sympathies and its well-deserved rewards, will continue to be the most attractive branch of medicine. Meanwhile preventive medicine must discover more and more efficient means of protecting individuals and communities against disease, and thus confer upon humanity benefits which, though inestimable, cannot evoke the same personal gratitude as successful treatment.

Problems Presented in the Control of Infectious Disease.

It is impossible for individuals to realise the extent of benefits the need of which they have not felt because they have been saved the pangs of disease; it is from the State that the recognition of such services should come. In the course of a few remarks which Dr. Arthur Ransome made on the occasion of the opening of this laboratory he said: "The health of the people is the supreme law not only for statesmen and law-givers but for the whole community. The Common Health comes before the Common Wealth, which, indeed, would be impossible of attainment without it." These words indicate the principle which must have guided legislators ancient and modern who have paid attention to the control of disease by legislative and administrative methods.[3] It is specially to this aspect of preventive medicine that the terms Public Health and State medicine are applicable. It is clear that sanitary laws are at most the expression of the knowledge available at the time of their promulgation; their usefulness depends on the soundness of that knowledge and on the possibility of making it applicable to the masses through some kind of administrative machinery. The medical advisers of sanitary authorities have, therefore, not only the task of contributing to the advance of knowledge, but they have also to see that this knowledge is adequately reflected by the sanitary laws which they have to administer. While the medical officer of health must be progressive he must also be patient, for the problems he has to deal with are very intricate. Thus, taking infectious diseases as an example, it must always be remembered that the occurrence of infection is not determined only by the essential causal agent, but also by the coöperative agency of various factors, of which, under special circumstances, some become so important that they more or less completely overshadow the essential cause. This is particularly noticeable in the case of diseases such as tuberculosis, of which the essential cause is a widely distributed microbe. If, whenever the opportunity of infection occurred, the tubercle bacillus were abundant or virulent enough, and its possible victims were in a receptive state, there would be very few persons free from tuberculosis among civilised communities.

The importance of predisposing factors is often so great that not a few clinicians and administrators have given but scant attention to the essential cause. It must be acknowledged that in many cases excellent results have been obtained by dealing thoroughly with predisposing causes, and that often, in the present state of science, no other course is open to us. It is, however, never safe to disregard, even temporarily or partially, the *causa causans*, because this essential factor may under the influence of various circumstances acquire excessive powers. Neither is it safe, for preventive purposes, to rely entirely upon the action of natural or artificial curative agencies, because these may fail. Recoveries from infectious diseases may be apparent or real, and do not invariably result in so great a reduction in the number of infective centres as might be expected. Recoveries brought about by natural processes are more common than is generally suspected, and, together with the existence of cases of infection without clear symptoms, introduce an additional element of complexity in our estimates of the occurrence and distribution of centres of infection. In studying the conditions which influence the prevalence of any infectious disease, and which must therefore be considered in connexion with prevention, it is necessary to take account of a great number of factors which may be roughly grouped into the following categories: distribution and habits of the infecting parasite; conditions influencing the quantity of the parasite; conditions influencing the virulence of the parasite; opportunities and channels of infection; conditions influencing the resistance of the possible host; conditions influencing the rapidity and completeness of recoveries.

I might show that with regard to non-infectious preventable diseases the problems to be solved are also very complicated, but what I have said of infectious diseases is sufficient to indicate that although public health has a very clear and well-defined object it cannot be called a science in the same sense as physics, chemistry, physiology, &c.

Scientific Training of the Medical Officer of Health.

To discharge his duties efficiently the medical officer of health should have some general and practical knowledge of certain branches of physics, chemistry, geology, botany, zoology, engineering, law, and statistical methods in addition to a fuller acquaintance with human physiology, pathology, clinical medicine, and epidemiology. It is clear that no man could be an expert in all these sciences, each of which has become more than enough to satisfy the energies of any modern scientific worker. The hygienist should, however, have a scientific training sufficiently broad to allow him to grasp the general meaning and relations of

[3] The development of sanitary legislation forms the subject of the very interesting and terse chapter on the Rise and Progress of Preventive Medicine in Dr. Hamer's Manual of Hygiene (pp. 1 to 15). London, 1902.

natural phenomena which may influence the occurrence of disease; he should also have some practical knowledge of the methods that are used in the study of these phenomena and of their relation to the occurrence of disease.

It is unfortunate that the choice of public health as a career is usually made only after the completion of ordinary medical studies, in which a considerable amount of time is devoted to subjects which are of little importance to the health officer, while little attention is paid to matters that are of the utmost importance in preventive medicine. If medical students who wish to enter the public health service could adapt the curriculum to their needs they would find it advantageous to devote the first three years of their studies to certain branches of physics, chemistry, geology, botany, zoology, human anatomy, and physiology, and should make themselves sufficiently conversant with mathematics to be able to work out some of the simpler physical and statistical problems. In the second part of the curriculum much of the time which is now given to operative surgery and to midwifery might with great advantage be devoted to the study of the etiology, pathology, and management of infectious and other preventable diseases. Under the present conditions candidates for the Diploma in Public Health have generally to make up in about nine or twelve months the deficiencies of the ordinary medical curriculum, and they must in addition study sanitary law, sanitary administration, vital statistics, and other matters relating to the duties of medical officers of health.

In order that this short period of post-graduate studies should meet the requirements of the public health student, it is obviously necessary that the teaching be so coördinated that each subject claims an amount of attention proportional to its importance. It is also desirable that the student should come in contact with teachers who have themselves an intimate practical acquaintance with the subject they teach. For reasons which I have already explained, I do not believe that any single teacher can be equally interested and competent in the various sciences bearing upon public health. It follows from this that in the short period of nine months the student should come in contact with a number of experts, and in order that this should not be a source of unbearable burdens it is essential that the various parts of the course should be well coördinated.

We have in this school striven, as far as was in our power, to follow this policy. With the coöperation and assistance of my colleagues I made arrangements some eight years ago for the teaching of the subjects of the first part of the D.P.H. examination which have, I believe, rendered the work of the candidates both easier and more profitable. On the occasion of the renaming of the chair which I hold, the University has sanctioned the extension of this method to the subjects of the second part of the D.P.H. examination. Under this new arrangement it will become possible for public health students to obtain in this laboratory from well-known administrators courses of lectures on sanitary engineering, sanitary law and administration, vital statistics, school hygiene, factory hygiene, and other special subjects which will render the study of these branches of administration simpler and more fruitful than in the past. Dr. Tattersall and Dr. Brindley will lecture on public health administration generally. Dr. Niven will deal fully with one subject, the administrative control of tuberculosis. The importance which school hygiene has acquired of late years is ample justification for the appointment of Dr. Meredith Young as lecturer on school hygiene.

With regard to factory hygiene, it is remarkable that a subject so important to industrial communities should have so long been unrepresented by a lecturer. The first course on factory hygiene will be given next summer by Dr. Legge, and you are to be congratulated on having the opportunity to listen to one who is so high an authority on the subject. I may add that the Home Secretary and Dr. Whitelegge have taken a warm interest in this extension of our work. I have also the pleasure of announcing that Professor Hickson will, for the first time, give in the laboratory a few lectures introductory to the study of animal parasites. This constitutes the only change which we have made with regard to the teaching of the sciences upon which the practice of public health is founded.

A Clinical Lecture

ON

HÆMATEMESIS.

Delivered at the London School of Clinical Medicine, Seamen's Hospital, Greenwich, on Oct. 10th, 1910,

BY SIR DYCE DUCKWORTH, BART.,
M.D. EDIN., LL.D., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE SEAMEN'S HOSPITAL.

GENTLEMEN,—I propose to discuss with you to-day some of the causes of gastric hæmorrhage, and the appropriate treatment for patients suffering from it. A case illustrating this subject has lately been in my wards, and affords a suitable text for this lecture. As you know, we have seldom female patients in this hospital, but as we receive emergency cases here, and an attack of severe hæmatemesis distinctly comes into that category, the subject of it was admitted on July 3rd. I will give you the particulars of it as concisely as I can.

ILLUSTRATIVE CASE.

A woman, aged 38 years, married, mother of a daughter aged 18 years, was taking a walk in the afternoon when she became faint and suddenly vomited nearly a pint of blood. She was much frightened and distressed on arrival here. She was put to bed and laid flat without a pillow. Her pulse was feeble, 104, and her respirations were 24. Her colour was good. No pain was complained of. A hypodermic injection of a quarter of a grain of morphine was given, and nothing by the mouth. A nutrient enema was administered. She passed a quiet night. There was a history of poor health and of continuous severe pain in the left hypochondriac region for two months previously, and of vomiting immediately after meals. Only light food could be taken. There had been no vomiting for three days before admission, and no blood had ever been seen in the vomited matter. Three years ago she suffered from indigestion for some time. She had always been very temperate and able to get good food. The family history was satisfactory.

Further examination next day showed that the heart's apex was in the left nipple line; the sounds were natural and the pulse was 96, of low tension. The mucous membranes were rather pale. She had several septic teeth and pyorrhœa alveolaris. The lungs were natural. The abdomen was in no pain, and no tenderness was caused by light palpation. The catamenia were regular. She was now menstruating.

In spite of absolute rest and avoidance of any food, not even water, by the stomach, there was a return of hæmorrhage. Morphine was repeated. On July 5th at 2.30 A.M. there was some nausea, and a little blood-stained mucus was brought up. She was fed only by enemata. On the 6th she had a little whey. Mr. Henry O. West ordered some bismuth and bicarbonate of soda in mixture. On the 7th at 9.30 P.M. there was a return of hæmorrhage in larger quantity. The morphine was repeated. Half a pint of saline solution was given per rectum every six hours. The temperature was normal. A nutrient enema (four ounces of milk, the yolk of one egg, and three drachms of glucose) was given every six hours. The rectum was washed out daily. No signs of blood were visible in the stools. The mouth was cleansed with antiseptics daily. The patient was not in the least thirsty, and had nothing by the mouth for three days. The tongue was cleaning. From this time convalescence advanced daily. Whey was found to cause some pain, and milk and water suited well in increasing quantities up to two ounces hourly by day and every two hours by night. Five grains of citrate of iron and ammonia in mixture were ordered on the 18th twice a day, and rectal feeding was stopped. Arrowroot and milk, beaten up eggs, and mashed banana were taken, then custard, milk jelly, and bread and milk. No pain was complained of. The patient was up and about early in August and left the hospital for the seaside on the 20th of that month, having gained weight and improved in colour.

There can be no doubt as to the nature of this case, and we may assume that there was an ulcer, or perhaps more than one, in the lesser curvature of the stomach which had existed for two months before any hæmorrhage occurred—

that is, before some small vessel, probably an arterial twig, was ruptured by the advance of the eroding ulceration. The recurrent bleedings are noteworthy. The first one occurred in spite of absolute rest and absence of all feeding by the mouth; not even a spoonful of water was given. The second one occurred after whey and milk and lime-water had been taken in small quantities, nutrition being maintained by enemata. As this was a more serious hæmorrhage, the question of surgical interference was discussed and arrangements were made for it in case of renewed bleeding. This happily proved unnecessary.

CLASSIFICATION.

Our knowledge in regard to gastric ulceration has been enlarged of late owing to the practice of modern surgery, and we are now able to classify these lesions under three conditions. We formerly recognised by the history and symptoms of gastric ulcers that they were acute and chronic; that some appeared to heal rapidly and gave no further trouble, while others proved rebellious to careful treatment. Inspections of the gastric mucosa on the operation table in some cases of severe recurrent hæmorrhage have revealed a lesion which had no resemblance to ulcer as commonly recognised in the post-mortem room, and conceived as existing beforehand. All that was apparent consisted in a series of small fissures, or chaps, from which blood oozed freely and continuously. Each of these being ligatured with fine thread ceased to bleed, and nothing further remained to be done; recovery followed. This oozing patch was regarded as an erosion, which, indeed, it appeared to be, hardly amounting to an ulcer. Cases of this kind have probably been regarded as instances of gastrostaxis, and we may assume that many of them cease to give trouble and heal kindly under appropriate treatment. We may fairly regard them as examples of a variety of ulceration, if we bear in mind the old surgical definition of an ulcer as a "solution of continuity." Some recent and careful observations by Dr. C. Bolton[1] of University College Hospital have shown that such erosions, although very difficult to find after death, may be detected by certain methods, and should certainly be regarded as superficial ulcers. It therefore becomes a question of degree. I confess that I am of his opinion in the matter. These lesions may be multiple, and it is certain that they are as apt to be serious sources of hæmorrhage as are the deeper ones. Mr. Butlin and I related a good example of this kind to the Clinical Society[2] in 1903, in which Mr. Butlin operated with advantage, and a rapid recovery followed.

TREATMENT.

The results of cases of gastric ulcer treated carefully in hospitals are, in the great majority, satisfactory, and have led some observers, Dr. W. P. Herringham[3] amongst them, to believe that in many of such patients there was probably no true ulceration present, but some much less serious condition. It may be that some of these patients were the subject of minor degrees of the superficial ulcerative erosion I have just described. Mr. C. Mansell Moullin and Dr. F. J. Smith have well described such cases. With regard to a fatal issue in all cases by hæmorrhage, I must add my experience to the effect that this is happily not a common occurrence. Whatever the lesion, or the degree of it, the treatment of the patient is the same, and it consists in absolute rest, recumbency with head low, and morphine given hypodermically. Nothing whatever is to be given by the mouth, not even iced-water or pieces of ice. Saline solution, in half-pint quantities, should be given by the bowel, and nutrient enemata consisting of from eight to ten ounces of peptonised milk, with yolk of egg and grape sugar, repeated three or four times each day for at least three days. The mouth should be cleansed with borax, thymol, and warm water several times a day.

We await the closing of any oozing vessel or arterial twig by clot, and this delicate process must not be disturbed by matters of any kind introduced into the stomach. These are apt to excite secretion of gastric juice which is unfriendly to a sore surface. Even nutrient enemata are apt to excite this secretion, as Dr. E. I. Spriggs[4] tells us, but the patient must be fed on something. After hæmorrhage, the next grave matter to bear in mind is the possibility of perforation of an ulcer, with alarming symptoms of pain and collapse, calling for immediate surgical action.

We may note that our patient suffered from some pain after taking small quantities of whey, and it may be that the excess of rennet in this may have acted as a peptic irritant. Milk and lime-water and cream are always safest for the first feeding by the mouth. An ice bag may be laid on the epigastrium during active bleeding, but should not be retained too long at a time.

I have said nothing so far as to medicines, save as regards morphine. We never use astringents now as was formerly the practice. Subnitrate of bismuth and calcined magnesia are the best to employ, a scruple of each, after a few days when the bleeding is stopped. The lower bowel should be washed out daily and the stools examined for melæna. Calcium lactate in 15-grain doses three times a day has been suggested, but I have not employed it, and adrenalin has been tried, but it was of no avail in one case of mine some years ago. I think that it is not a desirable agent in these cases, and I believe that in most cases we may dispense with any of these drugs if we carry out the physiological principles I have inculcated in every detail.

I should mention the desirability of performing gastro-enterostomy in cases where ulceration is found near the pyloric orifice on opening the stomach. The risk here is that pyloric obstruction may result from a scarred ulcer leading to dilatation and other difficulties. A subsequent operation for the relief of this may thus be avoided.

You are aware that many patients suffer from gastric ulcer without any hæmorrhage, or with very small bleedings. I am not concerned to speak about chronic ulcers to-day, and in regard to hæmorrhage from cancerous growth in the stomach I will only mention that we do not meet with this in persons under 40 years of age, and that there is seldom any serious loss of blood in such cases. Coffee-ground vomit is more common, and this may also be met with both in acute and chronic ulcers.

Apart from gastric ulceration, the most formidable cases of hæmatemesis that you are likely to meet with are those dependent on advanced cirrhosis of the liver. This is always a serious and often a terminal symptom in such subjects. The bleeding commonly occurs from rupture of varicose veins at the lower end of the œsophagus—œsophageal piles as they are sometimes called. The loss of blood is sometimes enormous, usually of very dark colour. Recurrence of it is almost certainly fatal. You will treat such cases just as you would any others. Happily, with the amendment now recognised in gross alcoholic habits, we do not meet with such examples so often as formerly. Melæna to a large extent occurs in these patients. The liver may be large, and is not always shrunken as might be expected when such an engorgement of the portal venous system is present.

Patients suffering from gastric hæmorrhage are always likely to do best in hospitals or nursing homes where they can secure skilled watching, and be saved from their own importunities and the dangerous meddling of relatives. The case I have related was tended with much skill and devotion by my house physician, Mr. West.

There are no specimens in our museum here to illustrate the superficial erosive ulcer. In the past these have been missed or overlooked at the necropsies for the reasons we have noted.

A CASE OF ACUTE PANCREATITIS; OPERATION; RECOVERY.

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL, AND CONSULTING SURGEON TO THE QUEEN ALEXANDRA MILITARY HOSPITAL, MILLBANK, S.W.

THE subject of acute pancreatitis in all its varieties has received much attention of late years, and the seriousness of the affection has been abundantly shown. So far, the records of cases successfully treated by operation are comparatively few, although it is fair to assume that most, if not all, of the recoveries have been published, while many of the unsuccessful attempts at relief have been left unnoticed. It is satisfactory, therefore, to be able to add to the list of successes one more case where prompt surgical interference has been followed by complete recovery. My own personal experience of operations for the condition is not large and

the case now to be recorded is the only one in which recovery has followed. I have, however, seen, I believe, several cases in too serious a condition to justify any hope of improvement by operation, which have therefore been left untouched and which have succumbed. The good result in this case was due as much as anything to the prompt action of the medical man in charge in sending so serious a case at once for surgical relief.

On Feb. 21st, 1910, Dr. C. E. H. Warren of Selhurst sent me a message that a case of some acute abdominal affection was on the way to the hospital. She was seen at once on arrival, and recognised as being in a very serious condition. I could only be sure of one thing—i.e., that a grave abdominal lesion, accompanied by peritonitis, was present and called for immediate operation. The hospital notes are as follows.

The patient, a married woman, aged 40 years, was admitted into University College Hospital on Feb. 21st, 1910. Two days before (the 19th) she was suddenly seized with a severe pain of a griping character in the upper part of the abdomen above the umbilicus. She vomited and "trembled" with pain, but apparently no definite rigor occurred. The pain subsided, but had returned in paroxysms from time to time, causing further sickness. The bowels had not moved since Feb. 18th; the patient could not say whether flatus had been passed or not. Before admission two enemata were given without result.

Past history.—Six years ago, one month after the birth of her first child, she had a similar attack of pain and vomiting with constipation, and, again, six months ago, after the birth of her last child, there was another attack like the first which lasted 48 hours. All pregnancies had been normal; there had been no miscarriages. The patient's husband thought that after the first attack she was jaundiced, but there was no jaundice with the last attack.

State on admission.—The patient was well nourished and had not quite the peritonitic facies. The pulse was 124 and the temperature was 101·4° F. The abdomen was soft and not fuller than normal. The patient complained of pain in the epigastrium and the left hypochondrium. In the last situation and in the left lumbar region there was tenderness on palpation. There was no dulness in either flank, and no loss of liver dulness was noted. The kidneys were not to be felt. The rectum was empty and distinct tenderness was experienced on palpation with the fingers on its left wall at the level of the fundus uteri. An enema produced no result. The urine contained no sugar, blood, or albumin. There was practically no shock on admission.

First operation.—A review of the history and condition on admission did not appear to me to justify any positive diagnosis. It was plain, however, that peritonitis was present from some sudden cause, the nature of which was obscure. In view of this fact I opened the abdomen in the middle line below the umbilicus at 9 P.M. There was some clear, slightly blood-stained fluid in the general peritoneal cavity. The pelvis was first explored, and only a burst Graafian follicle was found. The sigmoid was not distended and contained hard fæces. The vermiform appendix was normal. The small intestine was everywhere markedly injected and a little dilated, but was not paralysed. It was traced from the cæcum to the duodenum, and several flakes of lymph were found upon it. The condition was puzzling until I drew down the transverse colon, when several patches of fat necrosis were seen in the great omentum close to the colon 4 or 5 mm. in diameter. A portion of the omentum so affected was tied off and removed for examination and showed the fat necrosis still more clearly when treated subsequently by Benda's method. The omentum was now torn through between the stomach and colon, and the small sac of the peritoneum opened. In it were found many more patches of fat necrosis, increasing in number as the pancreas was approached. This organ itself was felt to be hardened and swollen, especially at its head. I did not think anything further could be done then, and simply introduced an iodoform gauze tampon down to the pancreas and brought it out of the upper angle of the abdominal wound, the rest of which was stitched up in two layers.

On Feb. 22nd the patient had slept well and had been easy. The pulse was 112 and the temperature was 99·4°. The bowels were opened twice during the day, the result being constipated. Saline injections were returned. On the 23rd fæces were still passed of normal appearance. The conjunctivæ were slightly yellow; there was no glycosuria; the tongue was very dry. The patient was fairly well, but was very weak. On the 24th she vomited after food. On the 25th some of the plug was removed. The patient was slightly jaundiced. On the 26th the remainder of the plug was removed; she was still jaundiced. On the 27th a clay-coloured stool was passed after calomel. The temperature was 100·2°. On March 1st stitches were removed. The temperature was rising at night to 100·2°. On the 3rd, at 6.45 P.M., the patient was seized with abdominal pain from the nipples down to the umbilicus. There was at the same time tenderness over the whole abdomen, most marked over the tip of the right ninth costal cartilage. The pulse rose to 124. The temperature fell to 98° at 10 A.M. Morphia was given, but the pain continued all day. She began to vomit at 4 P.M. and did so three times, bringing up 2 ounces. On the 4th she vomited several times, bringing up 12 ounces in all, but the general condition seemed better. In the morning the temperature was 100·4° and in the evening 101·4°. There was no increase of distension. The pain continued the same as on the previous day, but the point of greatest tenderness was now over the tenth rib on the *left* side and no longer on the right side over the gall-bladder. She now began to take pancreatin tabloids on account of fat in the stools. On the 5th there were more pain and tenderness, and she was weaker. The temperature at 10 A.M. was 101°.

It now appeared to me that there must be some exacerbation of the inflammation in the pancreas, and I thought of opening and draining the gall-bladder. But when the pain was overcome by a general anæsthetic a distinct fulness could be felt in the neighbourhood of the spleen where the tenderness had been most marked before. I therefore proceeded to try to open the omental sac behind from the left flank.

Second operation.—On March 5th an incision was made starting two inches to the left of the navel and running obliquely upwards and backwards. Extensive fat necrosis was found in the extra-peritoneal fat, and portions came away on the gloves and were reserved for further examination. The peritoneal sac was opened behind the splenic flexure of the colon below the spleen, and at once about 6 to 10 ounces of blood-stained fluid streaked with pus escaped under considerable pressure. This was followed by a pretty free escape of venous blood, which ceased on the introduction of a large long rubber drain-tube as far as the pancreas. The mass felt before operation was now proved to be the enlarged pancreas head. The spleen did not appear to be increased in size. A somewhat smaller rubber tube was introduced beside the first into the tissues of the loin outside the peritoneum, and the wound was partially stitched up from below. Sterile gauze dressings were applied over all.

On the next and the following days the condition was fairly good, the discharge from the wound being moderate. From this on there is nothing special to record until April 10th, except an irregular temperature between 100° and 101·4°, consequent, I believe, on some difficulty in retaining the drain-tube in the omental sac. The note on April 10th states that the patient had improved steadily; she was stronger and looked much better. The temperature, however, was never quite normal, and on the previous night had been 103·6°. The discharge from the tube in the omental sac had continued abundant, but fluctuated in amount. At 2 P.M. on this day the patient was seized with pain over the fundus of the gall-bladder. Tenderness was also most marked over this spot, but radiated over the whole abdomen, especially in the left flank. The pain was very severe and was only relieved by a full dose of morphia. There was no rigor. The temperature at the onset was 102°, but fell at 10 P.M. to 100·6°. The patient vomited seven times to the extent of 24 ounces during the night, but felt easier in the morning. The pain remained over a palpable mass to the left of, and below, the umbilicus (? undrained area). There was no icterus. From this time there was steady improvement, the drain-tube was progressively shortened, and was left out finally on May 17th, a dry gauze dressing being applied.

On May 20th a number of carious teeth were removed and some more on the 27th. The patient now appeared to be in excellent condition and was free from all pain. She was eating well and had much increased in weight. She was

therefore allowed to go home on May 31st. The temperature had been normal for 12 days and the wounds were soundly closed.

Remarks.—The difficulty of diagnosis in this case was very great. In some ways the attacks resembled recurring appendicitis. But the tenderness and resistance were on the left side and were more marked above than below; indeed, there were little tenderness and no resistance over the cæcum. That some grave intra-abdominal inflammation was present, however, there could be but little doubt, and what this was could only be cleared up by opening the peritoneal cavity. In this obscurity I felt it best to incise in the middle line and even then the condition was not clear until the fat necrosis revealed the true state of things. The white patches in the great and gastro-colic omentum, standing out in contrast to the fat lobules and slightly stained serous membrane, were unmistakeable. These increased in number when the bursa omentalis was opened. There was only a little blood-stained serum in the latter, but the pancreas was felt to be swollen and tender. Drainage of the omental sac appeared to me to be indicated as much on account of possible increase of discharge from breaking down of the pancreas as for the release of any present at the moment. As a matter of fact, this first drain opening yielded comparatively little and soon closed. This seemed to point to the conclusion that the condition was still mainly retroperitoneal. This was proved to be the case by the subsequent course of the disease and the finding at the second operation of extensive fat necrosis in the retroperitoneal tissues, so that these required a separate drain-tube for themselves. But it was not until the lesser sac of the omentum was opened behind the colon that a large collection of inflammatory fluid was found. The exacerbations which occurred even after this was drained off appeared to me to be due partly to the difficulty of retaining the rubber tube in the omental sac, the opening into which was only of about the size of my gloved finger. But it may easily be that they were due to progressive invasion of the pancreas by the inflammatory process even after efficient drainage had been secured. Before the swelling in the left hypochondrium was discovered I was tempted more than once to open and drain the gall-bladder. But I am glad now that this was not done, as the opening of the omental sac behind the colon in the left flank could alone have relieved the patient. It may be suggested that to have drained the gall-bladder would have possibly reduced the infection of the pancreas. But this is only a supposition. The old maxim, *ubi pus ibi evacua*, held good here, and I was glad of its guidance. The result at all events left little to be desired.

As regards diet in this case directions were given to have all the light fluid food sterilised in order to minimise the chances of further infection of the pancreas from the intestine.

An attempt was made to obtain a regular analysis of the fæces from the pathological department, but there were difficulties in this direction which could not be overcome. What was undertaken led to no definite results. The bacteria which were cultivated from the discharge obtained from the pancreatic abscess were streptococci. The peritoneal effusion met with at the first operation proved to be sterile on cultivation.

It is gratifying to be able to add one more successful case to the relatively few that have been recorded of recovery from this fell disease. Prompt and prolonged drainage appeared to be all that was required in this case for recovery, and the great increase of flesh and general well-being justifies the hope that this recovery will be permanent. The removal of decayed teeth, with the relief of the pyorrhœa alveolaris, and the use of a complete denture will also reduce the chances of subsequent infection considerably.

Sequel of the above case.—The subsequent history of this case adds, I venture to think, considerably to its interest. The patient, of whom I heard from time to time since her discharge from hospital, remained well up to the beginning of this month (October, 1910). On the morning of Oct. 14th last I was told that she had been readmitted with serious abdominal symptoms, which had set in on the 13th, and naturally thought of a recurrence of the pancreatitis. On seeing her she at once struck me as being very ill; her tongue and lips were dry; she was in great pain and looked pinched. The temperature was subnormal (98·2°), and the pulse 124. The pain was now in the lower part of the abdomen and the tenderness most marked in the left hypogastric region. The area in which the former pancreatic swelling had been situated was normal and both flanks were resonant. The question of strangulation by band following the former operation was considered and was thought probable. But remembering that pancreatitis may recur and that the symptoms of the previous illness were very like those now present, I thought the best course was to open the abdomen through the old scar in the left flank and to explore the condition from there. This was done on Oct. 14th, at 9 P.M., when empty coils were traced to the cæcum and very much distended gut to a congeries of coils held together by adhesions lying in the pelvis. The latter were drawn up with some difficulty after separating numerous adhesions and proved to be a volvulus twisted over some of the adhesions. When all the latter had been freed and free inflammatory fluid had been mopped out the contents of the distended gut were squeezed through the liberated volvulus into the empty gut and onwards into the colon and the wound was closed. But before this was done I took the opportunity of examining the pancreas with the fingers and found nothing abnormal to the touch except that the organ appeared to be smaller than usual. There was no trace this time of any of the fat necrosis so obvious in the former attack, and the urine and fæces which were passed later (17th) were normal.

The patient made a good recovery after some days of great pain and rise of temperature, and is now (Oct. 25th) looking and feeling very well, the wound being healed by first intention. The original attack in this case was not due to one of those fulminating processes in which wide sloughing of the pancreas occurs, from which, I believe, no recoveries under any treatment can be expected. But the suddenness and severity of its onset, with fever, peritonitis, and fat necrosis, justify its being placed among the acute cases. The opportunity of examining the abdomen *in vivo* some eight months after an attack of pancreatitis must be a rare one, and the absence of any palpable evidence of damage from the earlier inflammation of the pancreas encourages the hope that prompt drainage from behind may serve to arrest the disease in other cases.

Harley-street, W.

PHAGOCYTOSIS OF ERYTHROCYTES BY ENDOTHELIAL CELLS:

SOME POINTS IN CONNEXION WITH IT, AND A METHOD FOR ITS DEMONSTRATION.

BY W. O. MEEK, M.B., B.S. LOND.,
ASSISTANT DIRECTOR, LOUIS JENNER CLINICAL LABORATORY, ST. THOMAS'S HOSPITAL.

(*From the Pathological Laboratories, St. Thomas's Hospital.*)

OF previous laboratory experiments on the phagocytosis of red blood corpuscles, the greater number have been performed on the blood of animals artificially immunised to foreign erythrocytes. The iso-agglutinins (for erythrocytes) of human serum have been the subject of much investigation by Hektoen[1] and others. Such sera may be divided, as regards their origin, into two classes: (*a*) "natural" agglutinating sera, where the serum from a normal person agglutinates the red corpuscles of other normal individuals; and (*b*) "immune" agglutinating sera, where the sera from cases of disease agglutinate the erythrocytes of other diseased or normal human beings.

The power of such sera to bring about phagocytosis of the red corpuscles which they agglutinate has not been investigated to the same extent. Recently Dudgeon[2] has investigated the hæm-agglutinins, hæm-opsonins, and hæmolysins present in human blood sera. In the experiments to demonstrate phagocytosis he employed washed human leucocytes from normal and "immune" bloods. Out of a large number of observations he noted few instances in which phagocytosis of red corpuscles was present to a marked extent. At the conclusion of his second communication he states:—

In the concluding remarks in the preliminary paper on hæm-opsonins it was stated that "the experiments referred to in this communication entirely agree with the observations of Barratt and Keith, conducted

[1] Hektoen: Journal of Infectious Diseases, vol. iv., p. 297.
[2] Dudgeon: Proceedings of the Royal Society, Series B, vol. lxxx., 1908; vol. lxxxi., 1909; vol. lxxxii., 1909.

with the blood sera and cells from the lower animals. There was nothing to show that the agglutination, opsonic, or hæmolysing properties of normal or immune sera on red blood corpuscles have any direct relation to one another." From the investigations which have been made for this report, some of which have been referred to, it has been noted that a serum may hæmolyse, agglutinate, and incite phagocytosis of certain red cells, but although it may be capable of agglutinating and hæmolysing certain red cells, yet the degree of phagocytosis which is present may be negligible, or phagocytosis may be present without the other phenomena: on the other hand, a serum which has a high agglutinative value is more likely to give a somewhat similar incitor reaction than otherwise, although not necessarily.

Emery,[3] summing up the question of the identity or otherwise of thermostable opsonin and amboceptor, states:—

> There is an additional possibility that the part of a thermostable opsonin may be enacted by agglutinins. I believe that in the case of the hæm-opsonins of normal human serum the substance is a thermostable agglutinin with a second thermolabile zymotoxic group. Natural hæm-opsonic sera are, as far as I have seen, always powerful agglutinators of the red corpuscles which they opsonise, and when they are heated to 60° C. the opsonic power is destroyed, but the agglutinative faculty is unaltered.

In many diseases there are marked post-mortem evidences of red corpuscle destruction and phagocytosis in certain tissues, though such appearances are of extremely rare occurrence in the circulating blood during life. In such tissues the cells concerned in the phagocytosis are almost entirely "macrophages" or endothelial cells. The red corpuscles in such tissues may often be seen to be agglutinated into masses. The object of the present investigation was to determine whether these cells could be shown, *in vitro*, to evince a special aptitude for the phagocytosis of erythrocytes, and in what manner phagocytosis was related to the presence of hæm-agglutinins. Sleeswijk[4] and others have, in isolated instances, employed endothelial cells obtained from artificially induced effusions in animals, in connexion with experiments on hæmo-phagocytosis.

Technique.

The endothelial cells employed throughout this investigation were obtained from the ascitic fluid from cases of hepatic cirrhosis with ascites. Such fluids usually contain a high proportion of endothelial cells and may with care be obtained practically free from erythrocytes, a point of importance. The fluid was collected direct from the syphoning tube into sterile normal saline containing 0·85 per cent. of sodium citrate.

In the preparation of the cells a considerable bulk of fluid was centrifugalised in a water-driven centrifuge. The sediments from the various tubes were collected and re-centrifugalised. The deposited cells were then washed in two or three changes of normal saline solution, the mass of cells being gently broken up with a platinum wire between each washing. Finally, an emulsion of convenient density was made up in saline solution. In none of the ascitic fluids used did the centrifugalised cells show any appreciable phagocytosis of the erythrocytes present in the fluid, though such phagocytosis is occasionally very obvious. The endothelial cells so washed often shrink considerably in size and appear much smaller than when examined unwashed. The shrinking may render the cells difficult to distinguish from small lymphocytes in film preparations. The cells were used as soon as possible after, usually within eight hours of, their removal from the patient. On two occasions they were not used until 24 hours after withdrawal. In one of these cases their activity appeared unimpaired, in the other their phagocytic powers were somewhat reduced.

Attempts were made to obtain suitable endothelial cells from the guinea-pig either by scraping the cut surface of the spleen immediately after death or by the injection of sterile physiological saline solution into the peritoneal cavity. In the former case it was found very difficult to obtain an even emulsion of cells, and in the latter the number and nature of the cells present in the artificial effusion varied greatly.

The red cells employed consisted of 10 per cent. suspensions in normal saline solution of the washed red cells from a normal man and various cases of disease. The blood sera were obtained from normal persons and from a variety of hospital patients.

The phagocytic experiments were conducted by placing serum, erythrocytes, and endothelial cells in small lengths of glass tubing sealed at one end. The open end was covered with sealing-wax, and the tubes were incubated in the vertical position. They were placed in an air incubator at 37° C., and in nearly every case were left in the incubator for 30 minutes. By this method, the erythrocytes and the endothelial cells fall to the bottom of the tube and can be obtained, for purposes of making a film, with a minimum of fluid. Care was employed, in spreading the films, to avoid breaking up any agglutinated masses of red cells which might be present.

The agglutinative action of the sera upon the red corpuscles was investigated by incubating equal volumes of serum and washed red cells in a capillary pipette at 37° C. for 30 minutes. The microscope was employed in deciding whether agglutination was present or not. After this incubation the presence of hæmolysis was looked for. Apart from this no detailed investigation of the hæmolytic powers of the sera was made. In only one or two instances out of all the sera examined was a hæmolytic action noted under the above conditions (i.e., equal parts of serum and 10 per cent. suspension of erythrocytes at 37° C. for 30 minutes).

On the Power of Endothelial Cells to Ingest Erythrocytes.

The endothelial cells used throughout these experiments showed most marked powers of phagocytosis. They were able to ingest a large number of red corpuscles per cell—a fact partly due, no doubt, to their size. In the presence of a suitable serum the cells rapidly became packed with erythrocytes to such an extent as to render enumeration of the included cells impossible. To borrow a phrase from bacterial phagocytosis, almost every cell on a film was a "glutton." The loaded cells presented much the appearance of the phagocytic cells seen in the sinuses of a spleen where red cell destruction is going on. When the process of phagocytosis was watched on a warm stage the endothelial cells were seen to fill themselves with red cells within a few minutes to such a degree that the nucleus of the phagocyte appeared to be forced out of the cell through lack of room, and was seen projecting as a bud from the cell outline.

The process quickly reaches a maximum, and little difference in the degree of phagocytosis was noted when mixtures of cells, serum, and erythrocytes were incubated for half an hour or for two or three hours. The longest period for which such a mixture was incubated was ten hours. In this experiment the engulfed red cells were seen to be somewhat shrunken and to stain darkly, but no granules of pigment were recognisable.

This enormous phagocytic power of endothelial cells towards erythrocytes contrasts strongly with the behaviour of the large mononuclear leucocytes of the blood in Keith's[5] experiments. He states that occasionally these cells were seen to have taken up one or two red cells, but the extent of the phagocytosis shown by them was insignificant.

On the Relationship between the Agglutinating Power of a Serum for Erythrocytes and its Ability to Cause Phagocytosis of those Erythrocytes.

From the examination of a considerable number of sera it may be stated briefly that where any given serum caused agglutination of any given sample of washed red corpuscles, when this unheated serum was mixed with these corpuscles in the presence of a suspension of endothelial cells and incubated, the red cells were invariably ingested by the phagocytes. Conversely, in no case where a serum failed to agglutinate certain red corpuscles was it found capable of causing them to undergo phagocytosis. This held good whether the serum employed was an example of a "natural" or an "immune" agglutinating serum, and no difference in the hæm-opsonic powers of these two classes of sera was found, provided that the agglutinating powers of the two were equal. When the phagocytic experiments were negative they were conclusively so. The endothelial cells, in the presence of serum and erythrocytes (where such serum had no agglutinative action on the erythrocytes) showed practically no tendency to engulf the erythrocytes, and it was no uncommon thing to examine several hundred endothelial cells on a film without finding a single ingested blood corpuscle. Two examples may be cited:—

I. Of the sera from three cases of pernicious anæmia, A, B, C, serum A caused marked agglutination and great phagocytosis of red corpuscles from a normal individual. Sera B and C caused no agglutination of the normal red cells and *no* phagocytosis was seen on films.

[3] Emery: Immunity and Specific Therapy, p. 285.

[4] Sleeswijk: Ueber den Bau der Opsonine, Centralblatt für Bakteriologie, I. Orig. xlvi., 1908, p. 513.

[5] Keith: Proceedings of the Royal Society, Series B, 1906, vol. lxxvii., p. 537.

II. Sera D, E, F, from three normal males. Of these D was an example of a "natural" agglutinating serum and agglutinated the red cells of X (a normal man) strongly. It also caused great phagocytosis of X's erythrocytes. Sera E and F caused no agglutination and *no* phagocytosis of X's erythrocytes.

Throughout the experiments the extent of the phagocytosis brought about by a given serum was found to vary directly with the degree of agglutination which that serum produced on the red cells employed. Where agglutination was marked almost every endothelial cell was loaded with erythrocytes, so as to render its contents uncountable with accuracy; where agglutination was only slight the phagocytosis was correspondingly less.

In the majority of sera examined, and especially in those from normal individuals, the opsonic power of the sera was destroyed more or less completely by heating to 58° C. for half an hour. In such sera the agglutinating power may be little if at all impaired by this heating. The opsonic power can be restored by re-activating with fresh normal serum. The opsonin in "natural" agglutinating sera is then, as a rule, thermolabile, and its presence or ability to exert its action is closely related to the presence of agglutinins. Not all sera from apparently normal persons, however, lose their opsonic power on heating; one such serum retained its opsonin for erythrocytes after heating to 60° C. for an hour, though both its agglutinating and opsonic powers were considerably reduced. Such a "natural" hæm-opsonic serum contains a large amount of thermostable opsonin.

The effect of the hæm-opsonin present in a serum upon the endothelial cells was strikingly illustrated in films from the phagocytic experiments. In the presence of opsonin the agglutinated masses of red corpuscles are covered with endothelial cells, exhibiting a high degree of phagocytosis, and comparatively few endothelial cells are found lying loose on the film. There is no evidence of any agglutination of the endothelial cells, which are usually spread evenly over the clump of erythrocytes which they are ingesting. If, however, a serum containing thermolabile opsonin, and from which the opsonin has been removed by heating, be employed no such distribution of endothelial cells over the agglutinated erythrocytes is seen. The endothelial cells are scattered over the field and show no tendency to collect in the neighbourhood of the agglutinated red corpuscles. And this although the agglutinating power of the serum has been little, if at all, reduced by the amount of heating necessary to destroy the opsonin.

By employing the warm stage this attraction of the endothelial cells towards the agglutinated erythrocytes is very obvious and is seen to occur with considerable rapidity. On films where the agglutination of red cells is only slight and the clumps consist of but very few erythrocytes, only one or two phagocytic endothelial cells may be attached to each clump.

The following experiments serve to show how closely the degree of phagocytosis produced in a phagocytic mixture (erythrocytes, endothelial cells, and serum) is dependent upon the extent of red cell agglutination.

A. The serum used was from a case of bacilluria (B. coli) and showed a powerful agglutinative effect on the normal red cells. The hæm-opsonin this serum contained was thermolabile. In each case 1 volume of the serum or diluted serum was mixed with 1 volume of a 10 per cent. suspension of normal red cells and 1 volume of endothelial cells.

No.	—	Agglutination.	Phagocytosis.
I.	Unheated undiluted serum.	Very great.	Very great. Uncountable.
II.	Undiluted serum heated to 60° C. for 15 minutes.	Great.	50 cells contained 4 red corpuscles.
III.	Unheated serum diluted 1 in 2.	Great.	Uncountable.
IV.	Unheated serum diluted 1 in 10.	Slight.	50 cells contained 58 red corpuscles.
V.	Unheated serum diluted 1 in 20.	Very faint.	50 cells contained 9 red corpuscles.

The agglutination in IV. and V. was only visible microscopically. The serum being diluted before its admixture with the erythrocytes and endothelial cells, the actual strength of serum in II., III., IV., and V. was 1–3, 1–6, 1–30, and 1–60 respectively.

B. Serum from a healthy and presumably normal individual intensely agglutinated and slightly hæmolysed normal red cells (from another healthy man). The opsonin in this serum was largely thermostable. In each case the serum was mixed with equal volumes of suspension of normal erythrocytes and endothelial cells.

No.	—	Agglutination.	Phagocytosis.
I.	Unheated serum.	Very great.	Very great. Uncountable.
II.	Serum heated to 60° C. for 15 minutes.	Very great (less than I.)	Very great (less than I.)
III.	Serum heated to 60° C. for 60 minutes.	Slight.	50 cells contained 84 red corpuscles.

On adding normal serum (from the same source as the erythrocytes) to the sera in II. and III. and repeating the experiment phagocytosis was moderately increased in each case.

C. The serum of a rabbit immunised to human erythrocytes powerfully hæmolysed human red cells *in vitro*. It was inactivated by heat and considerably diluted to various strengths. Normal red corpuscles were agglutinated in varying degree by the various serum dilutions. They were then washed and mixed with serum (from the same source as the red corpuscles) and endothelial cells, equal volumes of the three constituents being taken. The serum employed (inactivated) caused agglutination, but no phagocytosis of human red cells in a dilution of 1 in 100.

No.	—	Agglutination.	Phagocytosis.
1	Erythrocytes agglutinated by inactivated serum 1 in 50, 1 volume. Normal serum, 1 volume. Endothelial cells, 1 volume.	Very great.	Uncountable.
2	Erythrocytes agglutinated by inactivated serum 1 in 100, &c.	Slight.	50 cells contain 51 erythrocytes.
3	Corpuscles agglutinated by inactivated serum 1 in 200, &c.	Very slight.	Slight phagocytosis where red cells were clumped.

In a similar manner an agglutinating serum with thermolabile hæm-opsonin was de-opsonised by heat and allowed to agglutinate normal red corpuscles, the serum being diluted so as to produce varying degrees of agglutination. The agglutinated red cells were washed and subsequently incubated with normal serum and endothelial cells. The phagocytosis varied with the degree of agglutination. Other experiments on the same lines as the above gave similar results.

Attempts were made to demonstrate the presence of phagocytosis by employing red cells and serum from the same case of disease. The patients from whom the blood was obtained were examples of those conditions in which marked destruction of red corpuscles is found after death—e.g., severe cases of typhoid fever and of pernicious anæmia. In no case, however, was any phagocytic effect obtained. In some cases where the endothelial cell emulsion included a few red cells, agglutination and phagocytosis were apparent, but, by substituting an emulsion free from blood, neither phenomenon was seen. For this reason a preparation of phagocytes free from red blood corpuscles is of great value in such investigations. In none of the cases in which the serum and red cells were examined for auto-phagocytosis was the phenomenon of auto-agglutination present, though, of course, many of the sera agglutinated normal red cells and the "immune" red cells were agglutinated by normal serum.

It seemed possible that phagocytosis of red blood corpuscles, by the action of their own serum, might be demonstrated if the washed red cells were exposed to the action of various toxic substances and then washed again and incubated with their own serum and endothelial cells. For this purpose normal red cells were incubated with diphtheria toxin and

others exposed to the action of dilute oxalic acid or hypotonic saline solution of such strengths as to produce faint hæmolysis; through suspensions of others coal-gas was passed. The subsequent phagocytic experiments were in all cases negative.

The effect of artificially agglutinating normal erythrocytes was also tried. N/100 HCl was the agglutinating agent employed. Washed normal red cells in 10 per cent. emulsion were incubated with N/100 HCl for 30 minutes. Subsequently the supernatant fluid was pipetted off and the agglutinated red cells were washed in several changes of normal saline solution, the tubes being agitated sufficiently to ensure thorough washing without breaking up the clumps of cells too much. The agglutinated cells were incubated with their own serum and endothelial cells. The ultimate agglutination was moderate in amount, and there was a considerable degree of phagocytosis, most marked in the region of the clumps of corpuscles.

This was repeated on several occasions with a similar result, though the amount of the phagocytosis was less than that obtained with agglutinating blood sera which produced a like amount of agglutination. Control experiments, using erythrocytes untreated with HCl, were, of course, negative, as also were experiments in which the serum was replaced by saline solution or by suitably diluted HCl.

In other experiments the red cells after agglutination with N/100 HCl were placed in contact with N/100 NaOH for 30 minutes, then washed and incubated with their own serum and endothelial cells. The action of the alkali was to increase the agglutination without making any appreciable difference to the degree of phagocytosis.

If dilute HCl be added to a mixture of serum, red corpuscles, and endothelial cells, the serum and corpuscles being from the same normal individual, agglutination and phagocytosis, both slight in amount, are produced. For example, normal red cells and normal serum from the same source, endothelial cells, and N/100 HCl (one volume of each) were incubated. The resulting film showed slight agglutination, and 50 cells contained 17 erythrocytes.

Conclusions.

1. That preparations of endothelial cells are especially suitable for observations on hæmo-phagocytosis.
2. Human blood sera, whether from "natural" or "immune" sources, which cause agglutination of other human red blood corpuscles, can be shown to also bring about phagocytosis of these erythrocytes by endothelial cells.
3. That the amount of "hæm-opsonin" in such sera is closely related to the amount of "hæm-agglutinin" which they contain.

I have to thank Dr. P. N. Panton for supplying me with material, and both him and Mr. L. S. Dudgeon for their advice on certain points.

SOME NOTES ON "DELAYED CHLOROFORM POISONING."

BY E. D. TELFORD, F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER HOSPITAL FOR SICK CHILDREN, PENDLEBURY.

OF the various post-mortem findings which are now regarded as characteristic of death from "delayed chloroform poisoning" the fatty liver is at once the most constant and most striking sign. The liver is large, of a bright yellow colour, and shows profound fatty changes in its cells. The extent of these changes has suggested to some writers that a morbid state of the organ must have been present before the administration of the anæsthetic. It is, however, unlikely that any grave abnormal condition of the liver could exist without yielding some clinical sign of its presence previous to the administration of the anæsthetic. Moreover, the changes in the organ, however marked, are but the total of the changes in its constituent cells, and such changes may well develop within the three or four days which precede death.

A case which happened in my practice recently proves that a fatal result from "delayed chloroform poisoning" is possible in a patient whose liver at the time of operation presented nothing abnormal to the hand or eye.

CASE 1.—The patient was a woman, aged 47 years, who had shown signs of pyloric obstruction for 17 years. She was in a weak and emaciated condition. The urine was not examined for diacetic acid or acetone. The operation disclosed a dilated stomach with pyloric stenosis due to healed ulcer and a posterior gastro-enterostomy was done. The anæsthetic was chloroform given on lint, and the administration lasted in all for 45 minutes. The liver was seen and handled at the time; it was absolutely healthy in size and appearance. For 36 hours the course of the case was normal, but at the end of this time vomiting began and continued without intermission till death. The later vomits were "coffee-ground." The pulse-rate gradually increased, delirium and restlessness developed, and there were ceaseless efforts to get out of bed until coma set in. The breath smelt of acetone, but unfortunately no specimen of urine was tested. There was no rise of temperature, and the abdomen remained flat and supple throughout. Death followed exactly four days after the operation.

At the post-mortem examination the abdominal wound and operation area were perfectly healthy. The liver was slightly enlarged; it was of a bright yellow colour, and on section showed an extreme degree of fatty degeneration. The organ was loaded with fat and was greasy to the touch. There was also definite fatty degeneration of both kidneys. These were the only signs found at the examination. I believe that this death was due to "delayed chloroform poisoning."

The opportunity of handling and inspecting a liver four days before death from "delayed chloroform poisoning" is almost unique, and the above case is of much interest, proving, as it does, that gross fatty changes may happen to a liver which had presented an absolutely normal appearance four days before death. This case may throw some light on the cause of death in some cases of gastro-enterostomy in which the patients die apparently from "exhaustion" within from three to four days of the operation. Many of the patients on whom gastro-enterostomy is done are in a state of starvation, and some have fairly advanced malignant disease. Both these conditions are well known as predisposing causes of acidosis, and it is at least likely that in some of these cases the administration of chloroform is sufficient to hasten the catastrophe.

The suggestion that "delayed chloroform poisoning" is an acid intoxication was first made by Brackett, Stone, and Low, and since the appearance of their important paper this view has received support from many writers. Of the various manifestations, that condition known as "recurrent" or "cyclic" vomiting has been most commonly selected as offering the closest analogy to the phenomena of post-anæsthetic acidosis. With some writers the symptoms occasionally seen after the administration of a general anæsthetic have been regarded as those of "recurrent vomiting" which has been precipitated by the anæsthetic. The analogy, close as it is, is yet far from complete.

Grave as the symptoms of "recurrent vomiting" may be, recovery is the rule and is often astonishingly rapid and complete, whereas a patient exhibiting the same degree of symptoms due to "delayed chloroform poisoning" will almost assuredly die. Death in "recurrent vomiting" is uncommon, and when it does occur happens only as the end of a series of attacks which have steadily increased in frequency and severity. Death in "delayed chloroform poisoning" is the rule and follows rapidly on a single fulminant attack. The post-mortem findings are different in the two conditions. In the few recorded instances of post-mortem examination in children dead from "recurrent vomiting" the appearances are very variable and the fatty liver which is so constant a feature of "delayed chloroform poisoning" is not always found. Much as "recurrent vomiting" and "delayed chloroform poisoning" resemble each other, likely as it is that they own a common pathology, it is evident that there is some radical difference between them.

It may be suspected that of the cases reported as due to "delayed chloroform poisoning" some, and these mostly the instances of recovery, are simply cases of recurrent vomiting precipitated by the operation or anæsthetic. In susceptible children attacks of "recurrent vomiting" are not infrequently excited by emotional causes. I have seen more than once a severe and typical attack ensue within a few hours of the reception of a rickety child into a hospital, and the case which I report below appears to be a clear instance of an attack of "recurrent vomiting" induced as the result of an operation.

CASE 2.—A male child, aged 5½ years, was admitted to the

Manchester Hospital for Sick Children suffering from a right inguinal hernia. The urine examined before operation showed no evidence of diacetic acid or acetone. A "radical cure" of the hernia was done under ether. The drug was given by an Allis inhaler after a preliminary induction of anæsthesia by 3 cubic centimetres of ethyl chloride. The total duration of the anæsthesia was 20 minutes, and 2 ounces of ether were used. On the patient's return to the ward he vomited once and seemed to recover completely from the effect of the ether. Nothing of note occurred until 36 hours after the operation, when the boy was noticed to be very stupid and drowsy. It is noteworthy that there was neither screaming nor restlessness. The temperature rose to 100° F. and the pulse was 120. Vomiting began during the night and continued for 30 hours, one of the later vomits showing some altered blood. The urine contained acetone, and the breath had the characteristic odour of the drug. The coma continued from the Friday night till early on the Sunday morning, when, with the cessation of the vomiting, the boy began rapidly to improve. By the Monday evening he was absolutely well. Acetone continued to be found in the urine for ten days in all.

There can, I think, be no doubt that this case was a severe attack of "recurrent vomiting," precipitated by the anæsthetic or by operation, and was not a case of post-anæsthetic poisoning. Owing to his alarming condition the boy's parents were summoned to the hospital, but when the mother saw him she said at once, with an air of obvious relief, "Oh! he will be all right soon. I have seen him like this often." Further inquiry elicited the fact that the boy was the subject of "recurrent vomiting," and he has, in fact, had some further attacks since leaving the hospital.

A review of the literature of "delayed anæsthetic poisoning" will show at once that the vast majority of the cases have occurred after the administration of chloroform, and that but few have been noted after the use of ether. It appears probable from both clinical and experimental work that any general anæsthetic induces a state of acidosis, and the relative immunity from untoward results shown by the ether cases is probably due to the fact that the danger lies more in embarrassed excretion than in increased production of the acid bodies, and that ether hampers the kidneys less in their work than does chloroform.

The risks attendant on the use of chloroform in operations for acute septic conditions of the peritoneum have been noted by several writers. It must have happened in the practice of every surgeon who has had much experience of abdominal work that a case of septic peritonitis, whether general or local, which gave rise after operation to no great anxiety, has quickly gone to the bad and the patient has died within two or three days of the intervention. This disaster may occur in the case of small and well-localised appendicular collections of pus. The abscess is easily reached, it may not be necessary to open the general peritoneal cavity, the friends are comforted by the assurance of a hopeful prognosis, and the patient is dead within three days. The first sign of trouble is vomiting, beginning without obvious cause, some 36 hours after the operation. The pulse-rate is a little quickened. The vomiting continues; treatment is without effect, yet the whole time the abdomen is flat, supple, and moves well. The further spread of any peritoneal inflammation can be excluded. Within a few hours of the onset of vomiting the patient's mental condition becomes clouded; there is some delirium, with restlessness; coma begins and deepens until complete. Meanwhile the pulse is becoming gradually weaker and more rapid. The breath smells of acetone and the urine gives the reaction for diacetic acid and acetone. The later vomits may be "coffee-ground." There is sometimes a slight icteric tinge. The breathing towards the end may resemble that of diabetic coma, to which, indeed, the general resemblance of the case is great. There may be a marked rise of temperature towards the close. The end comes in from 36 to 48 hours from the onset of vomiting, and there has never been throughout the case any local sign which would suggest an acute abdominal infection. The explanation of "appendicular toxæmia" is usually tacitly accepted, but if a post-mortem examination be made there is an entire absence of those signs which are commonly regarded as indicating a death from septic intoxication. The liver is large, and obviously very fatty; the kidneys are slightly swollen, pale in colour, and show the changes of cloudy or of fatty degeneration; the heart muscle is pale and of reduced consistence. On microscopic examination fatty changes are always to be demonstrated in the liver, usually in the kidneys, and often in the heart.

The cause of death is acid intoxication following the use of chloroform in an acute septic condition. I have during the past two years watched three such cases from the initial vomit to the post-mortem examination—one in my own practice and two in the practice of other surgeons. It is probable that in some cases in which patients die from acute septic conditions the action of the chloroform has added the last straw to the burden of a patient already fighting for his life against septic infection. There can be no doubt that many of the milder cases recover and so escape notice. Why here and there a case is picked out is, as with other instances of "delayed chloroform poisoning," the chief mystery of the condition.

Cases such as the above form a very strong indictment against the indiscriminate use of chloroform. Since my last report[1] of cases of "delayed chloroform poisoning" I have used ether in almost every case of operation occurring in my ward at the Pendlebury Hospital. The ether is given by the "open" method from an Allis inhaler after a preliminary induction of anæsthesia by ethyl chloride. I have used this method in over 800 cases and have always found it most satisfactory. The safety and rapidity of the method are of the greatest help where a large number of cases have to be crowded into the morning's work. The children whilst on the table are of a good colour and have never in a single instance given cause for a moment's anxiety. On their return to the ward the "sisters" report that these children vomit less than do the chloroformed patients, and that, if they do vomit at all, they do so within the first hour, and afterwards return very quickly to a fully conscious condition. No untoward after-effect has ever been noted. Lastly, it will be found that with increasing experience the supposed limitations of ether as an anæsthetic will recede almost to vanishing point.

Manchester.

A CASE OF POISONING BY ACONITE.

BY W. EDGECOMBE, M.D. LOND., M.R.C.P. LOND., F.R.C.S. ENG.

ON Oct. 15th, at 10 P.M., I was called to see a man, aged 60 years, who was said to have accidentally taken poison. On arrival at his hotel I found Dr. M. B. Ray and Dr. G. L. K. Pringle of Harrogate already in attendance, having been urgently summoned. We elicited with difficulty from the patient's wife, who was very deaf, the statement that the patient had, at 6 P.M., while alone, taken a dose of his medicine; had dressed and gone down to dinner at 7 P.M., and during the meal had felt very ill and appeared dazed and giddy. He had made no remark as to having noticed anything peculiar about his medicine. He was taken up to his room, undressed, and put to bed, when he speedily became unconscious. We found he had by him a mixture containing salicylate of sodium to be taken in effervescence with an acid julep; and a six-ounce bottle of liniment for external use, made up of one ounce each of lin. aconiti, lin. belladonnæ, lin. chloroformi, tinct. capsici, and two ounces of oil of gaultheria. It was supposed that he had taken one tablespoonful of his liniment in mistake for one of the julep; no one had seen him take it, but a tablespoon smelling of the liniment was found in a glass on the dressing-table.

The patient's condition was as follows. He was unconscious, lying on his back with a flushed face and stertorous breathing; he had convulsive clonic movements of both hands and arms, and occasionally of the legs and body; the eyes showed slow conjugate movements to right and left; the corneal reflex was absent; the pupils were of medium size, neither contracted nor dilated, and responded sluggishly to light; there was no sign of paralysis of the face or limbs. The pulse was rapid, 110, feeble, and of low tension, and the heart's apex was well outside the nipple line and the sounds were feeble. Not the faintest trace of the smell of gaultheria was noticeable about the breath.

The first question was, Had poison been taken at all, or was the case one of cerebral disturbance or uræmia? The evidence that poison had been taken was limited to the spoon smelling of the liniment; and this might well be explained by the patient having poured some out with which to rub

[1] THE LANCET, Feb. 29th, 1908, p. 623.

himself. There was no dilatation of the pupils such as would certainly have been expected four hours after taking a considerable dose of belladonna; nor was there about him any smell of wintergreen, the odour of which is so penetrating and characteristic as to be readily recognisable. We learnt afterwards that he had complained of distension and pain over the stomach region, but the symptom was not present at the time. The rapid feeble pulse was against cerebral hæmorrhage, but did not negative the possibility of thrombosis, though the absence of any paralysis was against both these. The absence of high tension of the pulse was against uræmia; moreover, a specimen of urine drawn off by the catheter was found to be free from albumin and sugar. On the whole, I thought the probability was that he had not taken the poison and that the symptoms were due to some obscure cerebral irritation. However, it seemed wise to wash out the stomach, although so long a period as four hours had elapsed since the dose was said to have been taken. The introduction of the stomach-tube promptly caused a copious vomit, which smelt strongly of wintergreen, and proved conclusively that the liniment had been taken.

The patient's condition was now somewhat critical; the pulse varied from 130 to 140, was extremely feeble, and at times was felt with difficulty; the extremities were cold and the lips blue, but the face retained a dusky flush; the convulsive movements were increasing. It seemed clear that the aconite was the poison mainly at work and was causing extreme depression of the heart. I gave the patient 10 minims of liq. strychninæ hypodermically and injected eight ounces of hot strong coffee slowly into the rectum, applied hot bottles, and wrapped him up in hot blankets. After about an hour, during which his condition gave rise to great anxiety, he began to rally, became semi-conscious, and rambled in his speech; the convulsive movements gradually ceased and the pulse became fuller and stronger and the body surface warm. At 3 A.M. his condition had so far improved that I ventured to leave him in charge of a nurse. The next morning he was better; the pulse, though still rapid, was of good quality, and beyond being somewhat dazed and shaken he expressed himself as feeling very well, and refused to believe that anything serious had happened. For the next few days, during which his only complaint was of numbness and tingling in the fingers, he was kept at rest in bed until his circulation had resumed its usual state, which showed itself to be one of high tension, bounding vessels, and hypertrophied heart. His recollection gradually came back of having noticed a pungent taste with tingling of the mouth after taking his medicine, but he thought nothing of it at the time, nor did it occur to him that he had made any mistake.

The quantities contained in the tablespoonful dose of the liniment were 40 minims each of lin. aconiti, lin. belladonnæ, lin. chloroformi, and tinct. capsici, with 80 minims of ol. gaultheriæ. The gaultheria and chloroform may be neglected as being insufficient in quantity to produce much toxic effect. The capsicum, beyond being irritant, would do no harm, and conceivably may have been salutary by acting as a reflex stimulant. There remain the belladonna and aconite. Forty minims of lin. belladonnæ would contain 0·15 grain of alkaloids (atropin and hyoscyamin mainly), or about 1-7th grain, the official dose of atropin being 1-200th to 1-100th grain. As compared with the tincture, the liniment of belladonna is eight times as strong. The maximum dose of the tincture being 15 minims, then 40 minims of the liniment would represent a dose 21 times greater than the maximum—i.e., about 5 drachms. It is a matter of surprise that so large a dose should have caused no dilatation of the pupils: it was this fact, together with the absence of the smell of gaultheria, that largely influenced me in doubting whether poison had been taken at all.

As regards the aconite, taking the recognised standard for aconite root as containing 0·5 per cent. aconitine, then 40 minims of lin. aconiti would be equivalent to 0·132 grain aconitine—i.e., about 1-8th grain, or 31 times the maximum dose, which is given as 1-250th grain. Put in another way, the liniment is 13 times the strength of the tincture, of which the maximum dose is 15 minims. In this case 40 minims of the liniment represent 35 times the maximum dose of tincture of aconite, or a dose of 8¾ drachms!

Bearing in mind the well-known extreme toxicity of aconitine, the patient must be regarded as singularly fortunate in having escaped with his life.

Harrogate.

A METHOD OF REMOVING NASO-PHARYNGEAL FIBROMATA, WITH TWO ILLUSTRATIVE CASES.

BY THOMAS GUTHRIE, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

AURIST AND LARYNGOLOGIST, VICTORIA CENTRAL HOSPITAL, LISCARD; CLINICAL ASSISTANT, THROAT DEPARTMENT, ROYAL INFIRMARY, LIVERPOOL.

NASO-PHARYNGEAL fibromata are somewhat rare growths presenting certain well-defined characteristics. They occur almost exclusively in the male sex between the ages of 10 and 25 years. They arise as a rule from the basilar fibro-cartilage, but more rarely also from the margin of the internal pterygoid plate and from within the spheno-palatine and spheno-maxillary fossæ. They grow with considerable rapidity always in the direction of least resistance, making their way into the neighbouring cavities, the walls of which become thinned by pressure and eventually give way. In spite of their clinical malignity they are benign growths and neither infiltrate nor cause metastases. As seen in the naso-pharynx they are smooth tumours of a pink colour, and to the touch they are almost always exceedingly hard. Histologically, they are composed of dense fibrous tissue provided, especially near their point of attachment, with numerous large blood-vessels, the presence of which accounts for the marked tendency to spontaneous hæmorrhage. If left to themselves they cause death from suffocation, intracranial invasion, hæmorrhage, or exhaustion unless the patient previously reaches the age of 25 years. At this age growth probably always ceases and not infrequently complete disappearance of the tumour has been observed.

During the early stages, when spontaneous hæmorrhage is often absent, the only symptoms are those due to nasal obstruction, so that the growth has not infrequently reached a considerable size before the patient comes under observation.

By the repeated employment of electrolysis or the galvano-cautery over a long period the growth may be kept in check until the patient reaches the age of 25 years or it may in very early cases be completely eradicated, but such measures are always extremely tedious and disagreeable to the patient, and not infrequently fail to attain their object. Complete removal by operation constitutes the only entirely satisfactory method of treatment, and in order to accomplish this steps must first be taken in all but the earliest cases to provide free access to the growth. Of such preliminary operations division of the soft palate, either alone or with removal of the posterior part of the hard palate and nasal septum (operation of Nélaton), has perhaps been more often employed than any other. This method, however, possesses the disadvantages of providing very imperfect access, and of involving the risk of subsequent imperfect closure of the naso-pharynx by the soft palate.

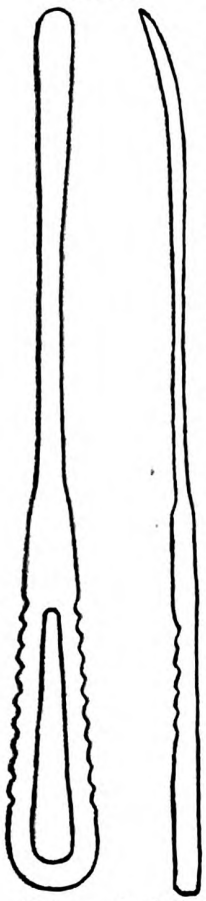
Exposure of the growth from the nasal aspect may be obtained by temporary resection or partial or complete removal of the upper jaw. These operations are, however, necessary only in advanced cases when the tumour is of very large size and has become firmly fixed to the walls of neighbouring cavities. As a general rule it is sufficient to adopt some method of enlarging the bony anterior nasal aperture (apertura pyriformis) in such a manner as to permit of the free use of a strong periosteal elevator passed through the nose for separating the naso-pharyngeal attachment of the growth. This enlargement may be effected by making an external incision along the angle between the nose and cheek, separating the soft parts, including the periosteum, and removing a sufficient amount of bone from the margin of the anterior nasal aperture. It occurred to me, however, that the facial scarring which this involves might be avoided and the necessary amount of bone equally well removed *from within* the nose by means of an incision through the muco-periosteum covering the inner aspect of that portion of the superior maxilla which forms the outer margin of the pyriform aperture. In each of the cases here reported this method was adopted and proved quite satisfactory, ample space being obtained with a subsequent complete absence of deformity.

As already indicated, separation of the growth is effected by means of an elevator passed through the nose assisted by

two fingers in the naso-pharynx. The instrument figured, which I have had made for the purpose, served very well (Fig. 1). It is considerably longer than the ordinary periosteal elevator, and has a curved end and a rounded tip with a half-sharp edge.

Hæmorrhage during the removal of these growths is usually very severe. In all but the earliest cases a preliminary laryngotomy must be performed and the pharynx plugged with a sponge. As pointed out by Brady,[1] the bleeding is least if the elevator in separating the growth is kept close to the point of attachment and the surface of the tumour is not interfered with. Separation must be conducted as rapidly as possible, since when it is completed the hæmorrhage usually ceases; if it does not do so a plug of iodoform ribbon gauze is required. Preliminary ligature of the external carotid artery is needed only in very extensive cases.

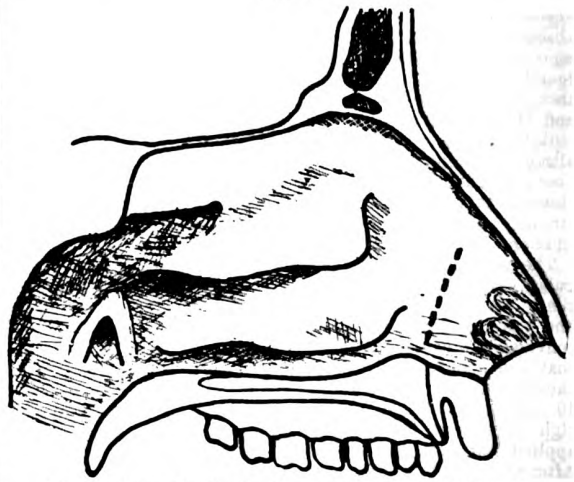
FIG. 1.



Elevator. One-half actual size.

During the last three years five cases of the disease have come under my observation, and in two of them it has fallen to my lot to remove the growth. In the first case, that of a boy 15 years of age, gradually increasing obstruction had been noticed for about two and a half years, and there had been two or three attacks of spontaneous hæmorrhage from the left nostril. Two unsuccessful attempts had been made to remove the growth on the assumption that it consisted of a large mass of adenoids. The growth filled the greater part of the naso-pharynx and a portion of it projected forwards into the left nasal cavity. Removal of a small piece for microscopic examination was followed by free hæmorrhage. The portion removed presented the typical histological characters of a naso-pharyngeal fibroma. In order to prevent hæmorrhage during the preliminary widening of the bony anterior nasal aperture, a submucous injection of a few drops of normal saline solution containing 4 parts in 60 of adnephrin solution (1–1000) was made, and cotton-wool soaked in adnephrin solution was applied within the left nostril. Laryngotomy was then performed, a tube was inserted, and the pharynx was plugged with a sponge. An incision was then made within the left nasal cavity in the situation indicated in the diagram (Fig. 2). The muco-periosteum within and the periosteum and soft parts without were easily separated with a sharp Freer's elevator, and sufficient bone removed with punch forceps to allow free movement of the special elevator during removal of the growth. (Fig. 3.) With two fingers in the naso-pharynx and the elevator passed through the left nasal cavity the attachment of the growth to the vault and the posterior and outer walls of the naso-pharynx was rapidly separated, and the mass seized with strong catch forceps and drawn out through the left nostril. During separation the sharp edge of the elevator was kept close to the bone so as to leave the latter quite bare after removal of the mass from its place of attachment. The hæmorrhage was very free, but it ceased shortly after removal was complete, and no packing was required. The laryngotomy tube was removed at once and the wound was closed. The growth was -shaped, the vertical or naso-pharyngeal limb measuring 1½ inches in length and the horizontal or nasal limb 1¾ inches. The growth appeared to have been entirely removed, but this proved to be not the case, as some four months later, left-sided nasal obstruction having returned, a similar operation proved to be necessary for the removal of another portion of the tumour. This was situated partly in the left half of the naso-pharynx and left nasal cavity, but mainly in a large cavity apparently representing the expanded spheno-maxillary fossa. Separation was rather difficult owing to the situation of the greater part of the tumour, but was effected partly by means of the curved elevator and partly by strong traction with catch forceps. The insertion of a gauze plug was required to arrest the hæmorrhage. The tumour on this occasion was rather larger than that first removed, being

FIG. 2.

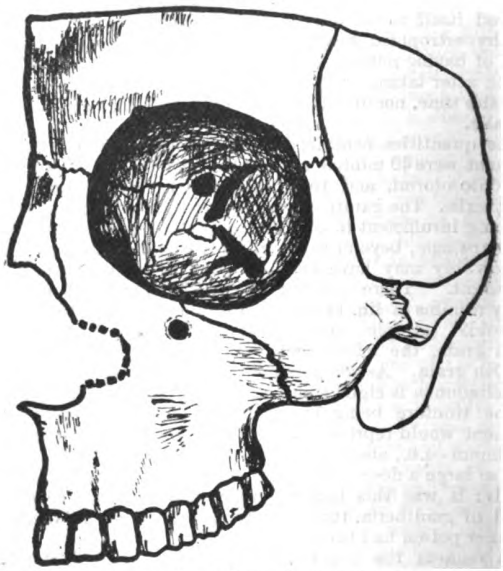


The situation of the incision through the muco-periosteum is indicated by the dotted line.

somewhat spherical in shape, with a diameter varying from 1½ to 2 inches. It represented, no doubt, a portion of the original mass which occupied the spheno-maxillary fossa. It is now more than a year since the second operation and there has been no recurrence of the growth.

In the second case, that of a boy 16 years of age, nasal obstruction had been present for about three years, and had

FIG. 3.



To illustrate the widening of the pyriform aperture by removal of a part of its bony margin. More bone than this can if necessary be easily removed through the muco-periosteal incision.

become so marked that the left side of the nose was completely blocked and the right very nearly so. There had been no spontaneous hæmorrhage. Removal was accomplished in exactly the same manner as in the first case, excepting that the growth after separation was removed through the mouth, being too large to be drawn through the nostril. Hæmorrhage was free during removal, but soon

[1] Journal of Laryngology, 1906.

ceased and no plug was required. The growth was L-shaped, consisting of nasal and naso-pharyngeal limbs measuring respectively 2½ inches and 2 inches in length. The attachment was mainly to an area about the left choanal margin, but partly also to the roof of the naso-pharynx. Healing was rapid, and up to the present time (six months after the operation) there has been no recurrence.

The method employed in these two cases is essentially that advocated by Brady, with the difference that the bony anterior nasal aperture is widened through an intranasal instead of an external incision. The operation would probably be suitable for all cases of naso-pharyngeal fibroma excepting, perhaps, those which have, before coming under observation, attained a great size with numerous offshoots in neighbouring cavities, for which some form of osteoplastic resection of the upper jaw may be required. The operation is, moreover, comparatively free from danger, involves no scarring or deformity, and permits of at least as complete a removal as any other method.

Liverpool.

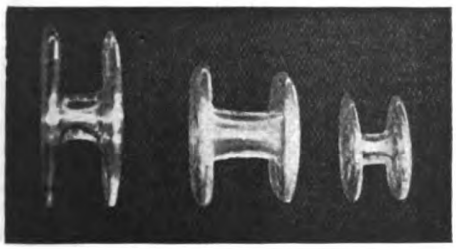
THE TREATMENT OF ASCITES BY DRAINAGE INTO THE SUBCUTANEOUS TISSUES OF THE ABDOMEN.

BY PETER PATERSON, M.B., C.M. GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

IN THE LANCET of August 15th, 1908, p. 456, I described a method of treating spina bifida by establishing a drain, composed of silk threads, between the subdural space and the subcutaneous tissues of the scalp. This is a modification of a somewhat similar method I have been using for draining the peritoneal cavity in cases of ascites. In this condition a drain composed of strands of material, such as silk, would not answer the purpose, as the end of the drain which projected into the peritoneal cavity would soon become encapsulated and so rendered useless. For this situation I employ a glass drain of such a shape that it will not slip into the peritoneal cavity. These drains or buttons are of various sizes, so that a suitable one can be chosen for each case.

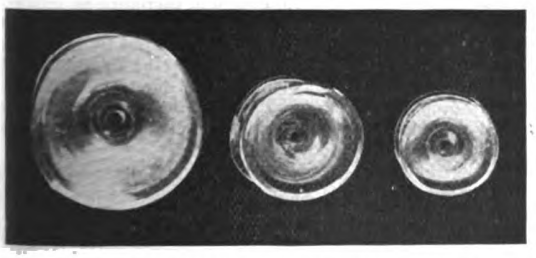
The buttons consist of a perforated glass cylinder expanded into a flange at each end. (Fig. 1.) The largest

FIG. 1.



size measures one inch across the flanges, three-quarters of an inch between the flanges, and has a canal one-twelfth of an inch wide. (Fig. 2.) The flange itself has a thickness of

FIG. 2.



about one-sixteenth of an inch. The diameter of the flanges and the width of the canal may be the same in the various sizes; but it is essential that the cylindrical part should vary in length, as this part has to pass through the thickness of the abdominal muscles, and as this thickness varies in different individuals so also must the length of this part of the button. In practice I have found it a convenience to have variations in the size of the flanges also, but this is not nearly so important as having gradations in the length of the cylinder. Care must be taken to have all the edges and corners rounded and that every part is perfectly smooth.

The operation is a simple one. An incision, about three inches long, is made in the middle line below the umbilicus, and the peritoneal cavity is opened in the line of the incision. If the abdomen has not been previously tapped the greater part of the ascitic fluid escapes at this stage. The omentum is now drawn down and removed at a level well above the point where the drain is to be placed, because, if left, it very soon passes into the opening in the drain and completely blocks it. The first case I did was a failure owing to my having neglected this precaution. The subcutaneous tissues are now dissected outwards, on one side, till the semilunar line is exposed, and through this an opening is made into the peritoneal cavity. This opening should just be large enough to permit the button being placed in position. The drain may be passed either from the peritoneal or subcutaneous side, but if from the latter care must be taken to avoid stripping the peritoneum from the edge of the opening when inserting the tube, or the flange may come to lie between the peritoneum and the subperitoneal tissues. By slipping one flange edgeways through the opening there is no difficulty in placing the button in position. When a suitable size has been chosen one flange should lie flat on the peritoneum and one on the abdominal aponeurosis, without any pressure being exercised on the intervening tissues. If too long, the apparatus would project into the peritoneal cavity, and the intestines might get nipped between the flange and the abdominal wall; while if too short, the button would tend to cut its way through the thickness of the tissues in its grasp. If the opening for the drain has been made too large and the edges do not grip the button firmly, a purse-string suture should be placed close to the button on the aponeurotic side, so that when tightened the soft tissues are brought into close contact with the groove in the drain.

The subcutaneous tissues are next closely stitched by a continuous suture to the anterior layer of the sheath of the rectus. This suture is placed about one inch from the margin of the primary incision and parallel with it. By this means the superficial end of the drain is shut off in a compartment of its own, and the fluid, as it escapes from the peritoneal cavity, is prevented from throwing too much strain on the suture closing the skin incision. The primary wound is sutured in the usual manner, the skin being closely stitched by a buttonhole suture to prevent any leakage. A collodion dressing applied to the wound gives additional support. This dressing is reapplied as often as required till the skin wound is firmly healed.

For one or two days afterwards the patients usually complain of pain round the neighbourhood of the button, but when this has passed off no further discomfort is experienced. If the quantity of peritoneal exudate be considerable a fluctuant swelling, almost of the size of the fist, forms within 24 hours in the subcutaneous tissues round the drain; but as absorption becomes established in the superficial vessels the swelling diminishes, till only a slight œdema remains to show that fluid is still escaping. When the exudate is small in quantity the swelling does not pass beyond the stage of œdema. It might be supposed that the intestines would adhere to the peritoneum round the edge of the button and thus shut it off from the peritoneal cavity, but in two cases which died several weeks after the operation, and in which a post-mortem examination was made, no adhesions were found and the peritoneum was quite smooth up to the edge of the opening; nor was I able to find, even after microscopical examination, any evidence of what might be possible, the peritoneum growing round the edges of the opening to the outer aspect of the drain and so encysting it.

I have performed this operation in several cases of ascites secondary to malignant disease, and also in cases of cirrhosis of the liver, with marked diminution of the abdominal distension, and to the great relief of the patients.

Glasgow.

PRELIMINARY OBSERVATIONS ON SOME CASES OF ESOPHORIA NOT CAUSED BY REFRACTIVE ERRORS.

BY REGINALD A. MORRELL, M.R.C.S. ENG., L.R.C.P. LOND.,

CHIEF CLINICAL ASSISTANT TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL AND CLINICAL ASSISTANT TO THE ROYAL LONDON OPHTHALMIC HOSPITAL.

AMONGST the large number of patients applying to the ophthalmic hospitals for relief from headache are many in whom the usual routine examination fails to disclose any refractive error to which their symptoms can be attributed. An examination into the condition of their muscle balance if carried out with a Maddox rod and candle at six metres will not disclose any abnormality. An examination under a mydriatic will also fail to discover any astigmatism or hypermetropia. These cases are, therefore, returned as normal and, in the event of a fundus examination revealing nothing abnormal, they will be advised that there is nothing in their eyes to cause the symptoms of which they complain.

This examination, complete though it may seem to be at first sight, is lacking in one important particular. The muscle balance at the time that the patient is accommodating for a near point has not been tried. If this addition be made to the routine examination it will not be long before the observer comes across a number of cases presenting the following clinical picture.

Type.—Usually nervous introspective persons engaged in a hard struggle for existence, or recovering from a serious illness, and who are constantly using their eyes for near work. The majority belong to that class from which neurasthenics are recruited, and, indeed, many show well-marked symptoms of that disorder.

Age.—Usually from 25 to 40 years. The youngest case seen by the writer was a girl, aged 18 years.

Symptoms.—Their complaint is always of headaches brought on by short periods of close work. The more intelligent will inform you that in reading the print soon becomes blurred, and that they have to close their eyes for a few moments before they can resume work. The relief thus obtained is, however, only of a temporary kind. These patients never complain of any discomfort when using their eyes for distant vision.

Examination.—The conjunctivæ are sometimes injected.

Vision.—Distant vision is good, 6/6 and often 6/5 being read with either eye.

Near vision.—As a rule no manifest hypermetropia or at the most only + 0·5 D. can be elicited. The smallest Jaeger type with each eye separately at a distance somewhat closer than normal. When tried with both eyes together any sustained effort to read fine print causes the symptoms of which the patient complains. The print is said to be blurred and the words to be all jumbled up. The patient is observed to hold the print closer to the eyes than normal.

The muscle balance.—Testing with the Maddox rod at six metres fails to discover any error in muscle balance, but the use of Harman's diaphragm test, the patient accommodating, at once discloses a condition of esophoria. A normal person if asked to read a row of capital letters seen through the diaphragm will do so with ease. The patients we are now considering, however, experience great difficulty and often fail to read the letters, which are described as "dancing about." The test has, in fact, betrayed a want of muscle balance which is always an esophoria. If whilst the patient is trying to read these letters a + 1 D. sphere is placed before each eye all confusion ceases, and the patient is enabled to read the letters without discomfort. This observation is repeated if the patient is given a pair of these lenses for reading purposes; comfort is at once restored, and reading can be continued for an indefinite period without fatigue or headache resulting, whereas without this aid a few minutes' reading suffices to produce such symptoms.

Examination under a mydriatic.—The mydriatic used by the writer has been, as a rule, the oily solution of homatropine and cocaine āā 2 per cent. This is instilled into the conjunctival sac, and in one hour a retinoscopy is performed, and no error of refraction is discovered.

To sum up, the only abnormality to be found by accurate testing in these cases is an esophoria when the patient is accommodating for a near point. This esophoria is at once relieved by placing a weak convex glass in front of each eye. The clinical picture presented in these cases is so uniform that a record of one serves for all.

The three following cases seen in private practice show that this class of case is not confined to the out-patient department, and are also of interest since they illustrate the three different types of patient who would seem to suffer from this form of esophoria.

CASE 1.—Patient, aged 29 years, complained of headaches when working. There were no headaches when she was walking about or when she was at the theatres. Vision = 6/6 right and left; no manifest hypermetropia. Jaeger No. 1 with each eye separately, but binocularly the print became confused almost immediately. No deviation with Maddox rod and candle at six metres. Diagram test showed esophoria. With a + 1 D. sphere before each eye the patient could read off the letters easily. Reading for a quarter of an hour with the aid of these lenses failed to bring on any unpleasant symptoms. Under homatropine and cocaine shadow turned with a + 1·5 D. in both meridians, right and left. Vision = 6/6 c. + 0·75 D. sphere right and left. Fundi normal. *Note:* This patient was a hard worker as a masseuse, starting at 6 A.M. and continuing to rush from one place to another till late at night.

CASE 2.—Patient, aged 40 years, unmarried. A very bad family history of delusions and insanity. The patient herself had suffered from "delusions" and during the consultation was observed to be very absent-minded. She complained of headaches on close work, but not at other times. Vision = 6/5 right and left. Manifest hypermetropia + 0·5 D. Jaeger type No. 1 with each eye separately, but with both eyes together this type was blurred. No muscular imbalance at 6 metres. With diaphragm test distinct confusion, relieved by a + 1 D. sphere before each eye. Fundi normal. The patient read newspaper print quite comfortably for some time with these glasses.

CASE 3.—Patient, aged 35 years, unmarried. History: Operation four months previously for appendicitis, and she had been "run down" since then. She complained of headaches when sewing and reading. Vision = 6/5 with both right and left eye. No manifest hypermetropia. Jaeger type No. 1 with each eye separately, but was confused when given binocular vision and complained of a "strained" feeling. With diaphragm test patient could only read the first two letters, the intermediate letters being confused. Ordered + 1·25 D. right and left for near work.

These cases, therefore, show that complete relief may be obtained by the use of weak convex glasses. The theory by which the writer endeavours to explain these symptoms will now be stated.

The error to be accounted for is, as we have seen, an esophoria. This particular form of imbalance can take the form of (1) an insufficiency of an abductor muscle, or (2) an over-action of an adductor muscle. In other words, it may be a divergence insufficiency or a convergence excess. In the cases which we are considering the fault is a convergence excess, for the patient presents the following characteristics of that condition: (1) there is no deviation for distance; (2) there is marked deviation for near vision; and (3) the near point at which the patient prefers to hold printed matter is closer than the normal.

It is a fact that accommodation and convergence are intimately connected; the stimulus for the former is, under ordinary conditions, the stimulus for the latter. Any unusual effort of accommodation must be combined with a strong impulse towards convergence. This fact, dependent upon the nerve supply of the muscles affected, was advanced by Donders to explain the occurrence of the convergent strabismus in hypermetropia.

In the cases now under consideration there is no error of refraction requiring excessive accommodation for its correction. It is, however, easy to imagine a state of fatigue affecting the ciliary muscle, a loss of tone, that is to say, similar to the general muscular fatigue so often complained of by these patients. The effect of this loss of tone would be a weakening of the response on the part of the ciliary muscle to the usual stimuli, and this in itself would lead to an increased stimulus being sent to the ciliary muscle, and at the same time to the adductor muscles. There would be an increased effort of accommodation, and therefore an increased effort to converge, or, in other words, an esophoria due to convergence excess. This theory is borne out by the clinical fact that a weak convex glass relieves the symptoms. As soon as the subnormal accommodation due to fatigue of the ciliary muscle is compensated for and the need for excessive stimuli eliminated, the convergence excess is replaced by the normal amount of convergence.

The writer ventures to submit this detailed account because, so far as he is aware, these cases are not described in any text-book, nor has their existence been widely recognised, if at all. The cases described are those which are diagnosed only when a test of the muscle balance during accommodation is made as a routine measure; even then success is only attained because the symptoms are promptly

elicited. This leads one to reflect on the possibility of there being cases in which these symptoms of fatigue do not manifest themselves until a longer period of time has elapsed, until, that is, the eyes have been accommodating for an hour or more. If this were so, it would account for many cases of asthenopia, the causation of which has not as yet been worked out, and the treatment of which is empirical and often unsuccessful.

At first sight these cases may seem to belong to that class to which the label "accommodative asthenopia" has been given. In the case of a patient suffering from "accommodative asthenopia," however, the symptoms are caused by the inability of the ciliary muscle to respond to *excessive* demands made upon it for the correction of hypermetropia. In the cases described in this article there was no excessive demand on the ciliary muscle and no error of refraction. It would seem that the ciliary muscle was unable to respond to ordinary requirements.

Such cases are more closely allied to those classed under the heading of "muscular asthenopia," where the symptoms are due to some kind of heterophoria. The usual description of such cases lays no stress on esophoria as liable to produce unpleasant symptoms, but exophoria is usually stated to be the most troublesome of these two conditions, and, moreover, is stated to be the one most usually found in emmetropes suffering from neurasthenia.

There are at least two reasons for insisting on the importance of these cases of esophoria, viz.: (1) the ease with which they may be passed over; and (2) the fact that they may be confused with cases of "retinal tire." The symptoms of "retinal tire" are in the main the same as those complained of by the patients whose symptoms are now being described. In each case there is a dimness of vision coming on after a short period of close work, rendering any further use of the eyes impossible until after a short period of rest; this, however, gives no permanent relief in either case. In cases of "retinal tire" it is the retina that is at fault, and no relief can be obtained with glasses. In the cases of esophoria, however, a glass at once relieves the patient and restores visual acuity.

The treatment of such cases by giving the required convex glass may be open to criticism, since by so doing one is relieving a symptom rather than treating the cause. In the writer's opinion the prescription of glasses should be combined with treatment by drugs. In the majority of these cases the patients are dependent for a living upon the constant use of their eyes for near work. They are unable to take prolonged holidays, and they demand, and have a right to expect, immediate relief if this can be given to them.

It may perhaps be argued that these cases are dependent upon the onset of presbyopia. It is difficult to see how this statement can be supported in the case of a girl, aged 18 years, seen at the Westminster Ophthalmic Hospital, and whose notes (published by kind permission of Mr. E. W. Brewerton) conclude this article.

CASE 4.—Patient, a girl aged 18 years. Complained of headache when reading. Vision = 6/5 in both eyes. Manifest hypermetropia of + 0·75 in each eye. Esophoria when tried with the diaphragm test. Relief obtained with a + 1 D. sphere in front of each eye. Unguentum atropinæ, 1 per cent., used three times a day for seven days. Retinoscopy shadows turned with a + 1·75 D. sphere in both meridians. Vision: 6/5 right and left c. + 1 D. These glasses ordered for near work. The patient reported in one month, and stated that all headaches had ceased since using the glasses.

Harley-street, W.

TWO CASES OF MALIGNANT PUSTULE.

BY L. A. PARRY, M.D., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, BRIGHTON.

A YOUNG Dutchman, aged 23 years, who had been in Hove only a few days, came in to see me one morning with a small sore place on the back of his right wrist. He said that about 18 hours previously he had noticed an itching sensation there, but it had not been very painful nor had it made him feel ill at all. On examining the wrist there was a small dark eschar with a ring of vesicles placed irregularly round it. There was marked œdema for some distance, and very distinct lymphangitis extending up above the elbow both back and front. There were very few constitutional symptoms. From the appearance of the primary lesion and the acute and rapid œdema I had no doubt that I had a case of anthrax. I excised at once a large area of skin and subcutaneous tissue, a circle about 1½ inches in diameter, which included the eschar and the vesicles and some surrounding healthy tissue, and painted the raw surface with pure carbolic acid. The patient made an uninterrupted recovery. The local symptoms began to clear up at once, and no severe constitutional signs appeared.

I was unable to trace the source of infection. The patient had nothing to do with leather, hides, or wool, nor had he been in contact with any horses or other animals. There is no anthrax in Hove, nor has there been any for years. Yet he must have been infected in the town, for the incubation period is generally a few hours or, at the most, does not exceed three days.

The second case is that of a man, aged 53 years, who was engaged in repairing baskets used in the foreign postal service. This work included the fixing of hinges and fastenings of strips of the skins of animals. He had a small pimple on his neck, which he scratched after working in some raw hides. From the small scratched pimple there rapidly developed a typical malignant pustule. There was a very considerable and rapidly spreading œdema round the anthrax pustule. The patient was sent by me at once to hospital, and the lesion was excised, but in spite of this he died a short time after.

The variety of external anthrax known as malignant pustule is generally (in this country in more than 99 per cent. of the cases) found on some exposed surface, such as the face, hands, or arms. Both my cases illustrate this. As to the source of infection in my cases, in the first I can find none of the usual causes, and I can only suggest that some unusual and unrecognised accidental handling either of an infected animal or infected animal product took place. As anthrax in animals is fairly abundant and frequent (in 1892 there were over 300 outbreaks in Great Britain, and seven of these were in Sussex), this is not difficult to imagine. In my second case the infection was almost certainly from the leather straps which the patient cut in the course of his work. This is, of course, an unusual source, but as he handled raw hides it is an easily explicable one. These hides were used untanned and were simply cut and soaked in water. A similar case had been known in the Post Office some years before. New regulations have been made since the second case by the authorities with the object of preventing its occurrence again.

The prognosis of malignant pustule depends very largely on the treatment adopted and the stage at which it is carried out. But there are other factors of importance; thus it is much more fatal on the neck than on other parts of the body. In this country, where the disease is rare and perhaps not always recognised at once, the mortality is high. During the years 1873–93 there were 115 cases of external anthrax in London, and of these 20 per cent. were fatal. Of the cases treated at Guy's Hospital at a later date, 1896–98, only 1 out of 26 proved fatal. The statistics of foreign countries are much more favourable. M. Le Roy des Barres had 72 cases, 57 in leather dressers and 15 in hair workers, and of these 62 recovered. Muskett of South Africa describes 50 cases with no death. His treatment consisted of ipecacuanha internally and externally. Mr. S. L. Woolmer of the Argentine Republic reports nearly 500 instances with only 2 deaths. Probably his unique opportunities enabled him to recognise the lesion at the very earliest stage. In this connexion the following extract from a letter from Argentine may be of interest:—

Here in camp, where one never sees a doctor, and when many of our peons often get anthrax during the summer, they do not die, and get well when treated by an ignorant native. Here when a man takes the infection it can be recognised at once as looking like an angry boil with a black or dark purple head; off he goes to a "curandera," generally an old woman. She takes a piece of thick wire, heats it red hot, and proceeds to burn away the centre of the boil. As the process goes on the flesh can be seen to burn away without feeling it till the sound part is reached.

The only treatment for malignant pustule that need be referred to is that which is practically universally adopted—namely, destruction of the primary focus of infection, either by caustics, the cautery, or the knife. The last of these is the best. It is that which is adopted at Guy's Hospital, where the results of late years have been very satisfactory. The pustule should be freely excised, with a good margin of healthy skin round and the raw surface painted with some strong caustic, such as pure carbolic acid. If this treatment is undertaken early the results are exceedingly good. Untreated cases are usually fatal within the week.

Prophylaxis is important. Unfortunately, very little can

be done for the external variety of anthrax. The wet cure of hides is largely adopted by the trade instead of the dry cure. It should be universal. For the internal varieties of the disease important regulations have been drawn up by the sanitary committee of the Bradford town council. These regulations, important as they are, are, in my opinion, not so good as those originally suggested by Dr. T. W. Hime, the medical officer of health of Bradford.

Hove.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF CHOREA TREATED BY THYROID EXTRACT.

BY PERCY A. RODEN, M.D. ABERD.,
HONORARY PHYSICIAN TO THE BRINE BATHS HOSPITAL, DROITWICH.

THIS case having caused me a considerable amount of anxiety, I publish it with the hope that others who have had similar cases may relate their experiences and so shed a further light on this very distressing malady.

The patient, a girl, aged 10 years, was brought to me three years ago with acute symptoms of chorea. Her restlessness was very marked, more especially in the arms and legs which were never quiet. The face and neck were very slightly affected. There were no facial twitchings, but an occasional jerk of the head to one side. The heart appeared to me quite normal; there was no murmur to be detected at the apex or at the base; the apex beat was not displaced, and there was no indication of any enlargement. I treated the child with arsenic in steadily increasing doses, at the same time giving gentle saline aperients (sodii phosph.), and ordering a simple diet which should be nourishing and at the same time not irritating—viz., porridge made of quaker oats, plenty of milk and cream, farinaceous puddings, vegetables, and ripe fruit. The child, however, showed no improvement. I ordered her to remain away from school, and commenced a course of treatment with potassium iodide, and as that gave no result I tried the combination of iodide with the bromide of potassium, still with no improvement. After having tried salicylates and quinine without good effect I took the child into St. John's Hospital for brine baths, and in a fortnight she was able to return home apparently well. She then returned to school, but in a month's time the jerky movements and want of coördination began to return, and the child became listless and showed signs of wasting. I ordered her once more to be kept from school, and prescribed cod-liver oil together with bromide and iodide of potassium, and then as she showed no improvement I took her once more into St. John's Hospital where she quickly lost her jerky movements, and was able to return home apparently quite well.

I was greatly in hopes that this second course of brine treatment would prove permanent. I did not see the child for some months, but was asked by the mother at the beginning of this year to call and see her, as she was worse than ever. Accordingly I went and found the girl suffering badly. Her mother begged me to take her once more into the hospital, which I intended to do, but while talking to her the other children (two girls) came in from school looking rosy and well, and I noticed that each of them suffered with goitre. I then examined the throat of my patient, but found no trace of goitre. I could not help thinking that perhaps she might have some thyroid insufficiency so I gave her teaspoonful doses of the fluid extract of the thyroid gland (prepared by Duncan and Flockhart of Edinburgh) twice a day with the most surprising result. The child showed marked improvement in the first week and returned to school in the second week, still continuing with the thyroid extract. With this she persevered twice a day for a month, and then was ordered to take it only once a day for the next month.

I have seen the child frequently and she looks rosy and well, showing no sign of chorea. This improvement has now been maintained for over nine months.

Droitwich.

A CASE OF CONCURRENT EXTRA- AND INTRA-UTERINE PREGNANCY.

BY FRANCIS W. DAVIDSON, M.B., CH.B. ABERD.,
LATE HOUSE SURGEON, ROYAL HOSPITAL, RICHMOND.

ON the morning of Feb. 9th of this year I was called in to see a woman, aged 32 years, who had been seized with a sudden sharp pain in the right side of her abdomen. I found the patient in bed in a collapsed condition. She was very pale and her pulse was small, rapid, and thready. Her symptoms and general appearance were those of internal hæmorrhage. The history was briefly as follows. She had not menstruated since the middle of December, 1909. At intervals during these two months of amenorrhœa she had sharp pains in her right side, but as they did not last long she had not sought medical advice.

On examination I found she was very tender over the lower part of her abdomen and quite dull in the flanks. I diagnosed ruptured ectopic gestation and ordered her immediate removal into the Croydon General Hospital. She was admitted under Dr. J. Wayte, who performed a right-sided cœliotomy the same afternoon. On examining the extracted ovum he found two fœtus of about two months' development. The patient made a good recovery and was discharged from the hospital on March 13th. About the middle of May she informed me that she thought she was still pregnant, as she had "felt the baby moving" since the end of April. I told her to come back and see me in a couple of months. This she did, and an examination left me in no doubt that she was about seven months pregnant. I gave her the middle of September as the probable date of accouchement and on Sept. 17th I delivered her of a healthy full-term female child. There was no trouble with the abdominal scar at the confinement and the patient had a perfectly uneventful puerperium.

Thornton Heath.

VASO-MOTOR RHINITIS OF 20 YEARS' DURATION; SUBMUCOUS RESECTION; COMPLETE RECOVERY.

BY CHARLES A. ADAIR DIGHTON, F.R.C.S. EDIN.,
HONORARY OPHTHALMIC AND AURAL SURGEON TO THE SCARBOROUGH HOSPITAL.

THE following case, which came under my charge early in April of this year, seems worthy of notice.

A well-built, particularly healthy-looking man, aged 30 years, came to me complaining of attacks of hay fever and rhinorrhœa occurring regularly every seventh day and completely incapacitating him from work on those days. He had been a butler, but owing to the disease had to give up his situation and is now a painter. Twenty years ago he had an attack of influenza and bronchial asthma, since which time he had had an attack of hay fever and rhinorrhœa every seventh day. He had been to several infirmaries and had had his frontal sinus opened and both sides of the nose cauterised with no effect. There was no history of accident or injury. On examination the nasal septum was found to be markedly deflected to the right side, showing a large bend in the superior portion and a large ridge on the vomer in the lower portion. The concavity on the left side was compensated for by a large middle turbinal. No polypi or pus was present, and the antrum was normal on transillumination. Under cocaine adrenalin anæsthesia I removed the nasal septum and ridge by the submucous method. The man returned to work on the third day after the operation and has continued at it ever since, with no sign whatever of any recurrence of the symptoms and has had no treatment whatever beyond a menthol spray after the operation followed by an alkaline douche, these being altogether stopped at the end of a fortnight.

The chief points of interest seem to be: (1) the antecedent bronchial asthma and influenza, probably setting up a condition of hypertrophic turgescent rhinitis in an already predisposed nasal cavity, the turgescence increasing for seven days and terminating in an attack of rhinorrhœa and hay fever; (2) the extraordinary periodicity of the attacks; and (3) the severity of them. Ballenger in his book notes a case of coryza œdematosa which appears somewhat similar, but in it the patient showed several œdematous spots, which

were entirely absent in my case, as the only signs present were a seemingly acute hypertrophy and turgescence of the mucous membrane during the attack, whilst between attacks the nose, except for deformity and enlarged turbinals, was normal in appearance.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

The Clinical Aspects of Metastatic Cancer of the Ovary.

A MEETING of this society was held on Oct. 24th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Mr. J. BLAND-SUTTON read a paper on the Clinical Aspects of Secondary (Metastatic) Cancer of the Ovary. He said that the subject of cancer of the ovary had interested him during a quarter of a century; during the whole of that period he entertained the gravest doubt in regard to the existence of primary cancer of the ovary. He was still in doubt concerning it. Observations published during the last eight years had established the fact that solid tumours of the ovary large enough to be perceptible to eye and hand in the hypogastrium, which on microscopic examination exhibited the structure of carcinoma, were nearly always secondary to primary foci of cancer in the breast, gall-bladder, or some part of the gastro-intestinal tract, especially the pylorus and colon. Many large solid tumours of the ovary, unilateral and bilateral, which exhibited the structure peculiar to cancer, and regarded as arising primarily in the ovary, were, in truth, secondary to cancer in some other organ. When patients were submitted to operation for solid ovarian tumours, especially if the tumours were bilateral and accompanied by vomiting and ascites, a careful examination should be made of the abdominal viscera, especially the stomach and sigmoid flexure of the colon. Some pathologists who willingly admitted that the solid cancerous tumours, such as had just been considered, were metastatic, still believed that many cystic ovarian tumours with a cancerous structure were primary. When cancer attacked the stomach, cæcum, or gall-bladder, the cancerous cells permeated the muscular and serous coats in relation with the primary growth and found their way into the general peritoneal cavity. Many of those cells were conveyed by the peritoneal fluid into the recesses of the pelvis and lodged on the ovaries, Fallopian tubes, and uterus. Cells which fell upon the ovaries implanted themselves, grew, replaced the ovarian tissue, and in some instances became large and easily recognisable tumours. From his observations he had come to the conclusion that when the cancerous cells implanted themselves upon a normal ovary the result would be a solid tumour, but it occasionally happened that cancer arose in the gastro-intestinal tract of a woman who had a cystic ovary. In such circumstances the cancerous particles implanted themselves on the wall of the cyst and grew quickly into large and formidable masses. In addition he had to add the Fallopian tube. Primary cancer of the Fallopian tube was a very malignant form of cancer, and the operative treatment of this disease had rarely been followed by enduring success. It was a well-known fact that when the mucous membrane of a Fallopian tube was infected with pathogenic micro-organisms, the changes in the tubal tissues resulting from such infection led to the complete occlusion of the cœlomic ostium of the tube. Some years ago he was able to demonstrate that an occluded ostium occasionally occurred in cancerous Fallopian tubes and that the closure of the mouth of the tube exercised an important influence on the course of the disease. When the ostium of the tube remained open the cancerous particles were poured out cornucopial fashion into the pelvis, and soiled all the adjacent tissues and organs. Nearly all the patients who submitted to operation for the removal of a cancerous tube, in whom the mouth of the tube remained open died with recurrence of the disease within a year. It must not be imagined that the implantation of cancer on the walls of ovarian cysts was an uncommon event. Within a period of 18 months (from March, 1909, to October, 1910) seven examples had come under his observation. The primary foci were distributed among the following organs: stomach, 2; hepatic flexure of colon, 1; sigmoid flexure of colon, 1; uterus, 1; Fallopian tube, 1; and in 1 the primary focus was undetermined. The question naturally arose as to the advisability of operating in many cases of that kind. The same argument applied to operations performed for the relief of cancer in any situation. When patients came under observation with a tumour of the size of a football in the lower half of the abdomen which was interfering with the bladder, the rectum, or both those organs, producing pain and great distress, perhaps accompanied by vomiting, the surgeon was bound to give the patient relief. No surgeon hesitated to perform colotomy in patients with acute intestinal obstruction caused by cancer in the upper part of the rectum. The surgeon would rarely have any difficulty in satisfying his conscience concerning the necessity of an operation, but he would at times be sorely tried when determining how much or how little he should remove. On several occasions he had removed bilateral ovarian cancerous masses and the uterus, and in the same operation removed a cancerous obstruction in the sigmoid flexure and joined the ends by circular enterorrhaphy. In some instances the patients had survived the operation and lived in comfort two or more years. It was more common for death to ensue within a year of such an operation. One of the most striking features in the after-history of patients from whom malignant ovaries had been removed was the rapidity with which the cancer recurred in the pelvis, even in cases where the uterus and pelvic peritoneum seemed free from infection at the time of the operation. When surgeons removed bilateral ovarian tumours which appeared to be malignant, they should carefully examine the gastro-intestinal tract, the gall-bladder, and the Fallopian tubes for evidence of primary cancer. If the disease was in a situation favourable for excision it should be removed; and if there was no obvious evidence of dissemination beyond the pelvic organs, it was a useful proceeding to remove the uterus as well as the ovaries. When the primary disease was too advanced for removal the patient's condition was often made more bearable, if not comfortable, by the removal of the ovarian masses, but it must be borne in mind that in attempting to do that the lives of patients were often shortened. Finally, a prolonged study of the question strengthened the conviction he formed many years ago, that primary carcinoma of the ovary remained unproven.

Dr. BERNARD H. SPILSBURY read a paper on the Pathology of Certain Ovarian Tumours, and in the course of his remarks said that he had encountered malignant metastatic ovarian growths only in very bad cases in which the peritoneal cavity had been flooded with cells.—Dr. F. J. MCCANN said that in the light of recent researches it was the duty of surgeons to examine carefully for a primary cancer in these cases, but it was to be remembered that some of these patients were in a desperate condition.—Mr. J. D. MALCOLM said that so far as solid tumours were concerned he was inclined to agree with Mr. Bland-Sutton.

OPHTHALMOLOGICAL SOCIETY.

Marginal Keratectasia.—Colloid Excrescences of the Membrane of Bruch.—Endothelioma of the Orbit.—Exhibition of Cases.

A MEETING of this society was held on Oct. 20th, Dr. G. A. BERRY, the President, being in the chair.

Mr. GEORGE COATS described the pathological features of a case of Marginal Keratectasia formerly shown to the society by Mr. J. H. Fisher. They consisted essentially in a loss of the superficial lamellæ in the periphery of the cornea, and their replacement by a loose vascular fibrous tissue. The membrane of Descemet had undergone enormous compensatory thickening and showed many ruptures plastered over with new layers of hyalin substance. In one area the epithelium was œdematous and desquamating, either as a result of commencing ulceration or of leakage from the anterior chamber. From a study of recorded cases it was shown that marginal keratectasia is usually the result of "furrow keratitis" (Schmidt Rimpler) or "marginal atrophy of the cornea" (Fuchs), a condition in which, without ulceration, a groove develops in the upper periphery of the cornea, usually between an arcus and the limbus; ectasia, distortion of the cornea, and astigmatism, against the rule, were produced by the giving way of the floor of the groove. As to pathogenesis there were two opinions: (1) that the condition was purely degenerative; and (2) that it was

inflammatory. In favour of the first there was the common absence of injection clinically and of round cell infiltration microscopically, as well as the association with arcus senilis; in favour of the second, the occasional presence of injection and even photophobia, or of pseudopterygium or pterygium, and the fact that vessels crossed the floor of the groove. Actual ulceration was probably excluded by many cases carefully watched over long periods. It was possible that a combination of these two explanations was correct—viz., that the products of degeneration set up a low form of inflammation, or that a low form of inflammation induced degeneration.

Mr. COATS also read a paper on an Unusual Instance of Colloid Excrescences of the Membrane of Bruch. The case was reported chiefly because it afforded an opportunity, rarely obtained, of comparing an ophthalmoscopic appearance with its histological foundation. The patient, aged 58 years, was achondroplasic and had glaucoma in both eyes. V.R. = fingers at 3 feet H. +7 D. V.L. = perception of light. In the right eye the media were fairly clear, and the fundus was strewn in every part with flat, scaly, irregular, white or grey areas, with a slightly wavy surface, and with distinct glitter on moving the light. The borders were sinuous and rimmed with pigment; pigmentation also occurred on the surface, especially towards the periphery. The choroid generally was degenerate. In the left eye there was a detachment of the retina; this eye was subsequently excised. Pathological examination showed that the areas were due to an aberrant type of colloid excrescence of the membrane of Bruch. In addition to the ordinary rounded forms, flakes and irregular spongeworks of colloid material were found. The choroid was very degenerate, and showed evidence of the former presence of a flat detachment. All the measurements of the globe were notably small, and in other respects a degree of infantilism was suggested. The relationship of these conditions with the glaucoma was discussed. The glaucoma itself was peculiar in that there was no adhesion of the corneo-iridic angle, and so far as could be seen no hindrance to drainage. It was suggested that the rise of tension might be due simply to a disproportion between the secretion and the amount of drainage available—normal so far as it went, but insufficient. The other eye, however, though glaucomatous, was not unduly small, at least in its external measurements. Another possibility was that the iris root had been in apposition with the ligamentum pectinatum, but not adherent, and had come away in the fixing fluids. Or there may have been an alteration in the chemical nature of the fluid to be drained. The pathology of glaucoma with open corneo-iridic angle was also discussed.—The papers were commented on by Mr. E. TREACHER COLLINS, Dr. C. MARKUS, and Mr. J. HERBERT FISHER.

Mr. LESLIE J. PATON communicated the later history of a case of Endothelioma of the Orbit. The growth was removed, but as it recurred locally the orbit had to be eviscerated, and the lymphatics leading down to an affected gland excised. Subsequently there was further invasion of glands in the anterior triangle; and when these were removed a further involvement took place above the clavicle and in the axilla. The patient ultimately died from a very large intrathoracic development. The growth was stated to be pathologically a simple endothelioma.

The following cases were shown:—

Dr. MARKUS: A case of Peripheral and Central Bulging of the Cornea; also a case which presented Unilateral Retraction of the Upper Lid and von Graefe's Sign.

Mr. C. S. BLAIR: A case of Endothelioma of the Lacrymal Gland.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Sleeping Sickness.

A MEETING of this society was held on Oct. 21st, Professor RONALD ROSS being in the chair.

Dr. ARTHUR W. G. BAGSHAWE read a paper on Recent Advances in Our Knowledge of Sleeping Sickness. He said in regard to etiology that an important piece of negative evidence had come to hand. The islands of Principé and San Thomé were a few miles apart in the Gulf of Guinea. They had a similar population, similar vegetation, the same climate. Principé contained tsetse-flies, San Thomé did not. On Principé there was much sleeping sickness; of nearly 2000 persons examined by the Portuguese Commission 23·5 per cent. were found to be infected. On San Thomé, though three months were spent there, the members of the Commission were unable to find a single case; and that was not due to want of opportunity, for cases of sleeping sickness were frequently imported into each island. On San Thomé, moreover, they found all the blood-sucking insects which they had seen on Principé, with one exception, the genus Glossina. That was to his mind presumptive evidence that in nature transmission of sleeping sickness occurred only exceptionally, if at all, in the absence of tsetse-flies. It confirmed the old observations in the West Indies and on the American continent, and supported the belief that sleeping sickness would never spread in a country where there were no tsetse-flies. Could they still adhere to the belief that among the tsetses the species palpalis was the only carrier? Until quite recently it appeared that they could. Unfortunately, in Northern Rhodesia and Nyasaland sleeping sickness had in several cases, European as well as native, been there contracted, and they were practically certain that Nyasaland, if not the Zambesi and its tributaries, was outside the area of distribution of Glossina palpalis. That suggested that another species of tsetse-fly might be capable of acting as carrier. But if sleeping sickness was really being diffused in Rhodesia by tsetse-flies other than palpalis, why had the disease not spread in East Africa by the agency of Glossina pallidipes and fusca, or on the high ground in the Katanga by that of Glossina morsitans? He suggested as a provisional hypothesis that it was because on those uplands the air was too cool and too dry to admit of the parasite completing its development in the body of the insect. To the suggestion that Glossina morsitans might be responsible for those infections it might be objected that the cases were few and scattered, whereas the disease should spread rapidly in places where a carrier was so abundant and so bloodthirsty, but it was very surprising to notice, even in the case of Glossina palpalis, the slow rate at which the disease spread in the most favourable circumstances. Since Kleine opened a new road to investigators by showing that tsetse-flies could, after a latent interval, be permanently infected with pathogenic trypanosomes, their knowledge of the subject had grown, but it could not be said that it had reached finality. That such late development was the rule in the insects which transmitted trypanosomes from mammal to mammal seemed probable. When the development of the trypanosome in the fly was discovered the non-infective interval appeared to be a definite fixed period. A long series of experiments carried out by the Sleeping Sickness Commission seemed to demonstrate that it might be very variable. They were still in the dark as to what went on in the insect during the non-infective period. The fact that the trypanosomes in the alimentary canal were infective went to show that there was no invasion of the body fluids and afterwards of the salivary glands. There was no evidence that Trypanosoma gambiense was infective to the tsetse-fly at any one stage of its life-history more than another. No observer had obtained any evidence of germinal infection. There seemed to be no such thing as hereditary transmission in the fly of those trypanosomes which were pathogenic to mammals. Perhaps the most striking discovery was that of Bruce and his colleagues in Uganda, that the flies caught on the shore of the Victoria Nyanza, cleared of inhabitants for some two years, were able to infect monkeys with sleeping sickness. Administrators had nursed the hope that the flies, compelled to feed on the lake shore vertebrates rather than man, would soon lose their infectivity, and then it would be possible, they supposed, to plant the same or a different population on the shore without risk. That would, in any case, have been a dangerous step in view of the difficulty of discovering infected persons, but now the idea must be quite given up. If it were definitely proved that wild animals formed a reservoir of the sleeping sickness virus, it was plain that all places where such animals and the sleeping sickness fly coexisted would be uninhabitable by man till the circle was broken by the extermination of either the vertebrate or the invertebrate host. Though no cases of infection by sexual coitus had been recently reported, experimental work suggested that it might occur. In regard to diagnosis more observations had been recorded on auto-agglutination, but they did not yet know the cause of

the phenomenon. Todd found that it was at its maximum just after trypanosomes had been numerous in the blood; if that were generally so, the curve of auto-agglutination might follow that of periodicity. Todd had published a table showing the proportion of cases in which trypanosomes and auto-agglutination respectively were found in 1406 persons examined on a single occasion in the Congo State. It showed that, while auto-agglutination might be absent when trypanosomes were present, of cases in which the corpuscles clumped a large proportion harboured trypanosomes; thus when agglutination was present 183 persons had trypanosomes and 212 had not; when it was absent, the figures were 24 and 987. The association of that phenomenon and trypanosome infection in man was thus well shown. It remained, therefore, true that well-marked clumping of the red corpuscles in a person who had visited or resided in an infected area was a phenomenon which should lead the observer to make repeated search for trypanosomes. The discovery of the trypanosome in one or other of the body fluids remained the only certain means of unmasking a trypanosome infection. Concerning the symptoms, an analysis in 50 published cases of sleeping sickness in Europeans showed that the most frequently recorded were, in descending order: fever, erythema, loss of strength, increased frequency of heart beat, somnolence, œdema, large spleen, anæmia, headache, and epileptiform convulsions. In the last 12 months no new trypanocide had come into use for treatment unless it were aniline antimonyl tartrate. They had learned little more as to the use of arsanilates such as atoxyl and soamin. Arseno-phenylglycin promised to be superior to either, but the data were as yet incomplete. The most favourable reports of the drug came from Togoland, where in Dr. von Raven's hands the results were good. It must be premised, however, that sleeping sickness in Togoland seemed more amenable to trypanocides than sleeping sickness on the other side of the continent. In German East Africa Eckard had much less success, but as he did not give the drug in the right way they might disregard his results. Von Raven had followed the method insisted on by Ehrlich of giving one or two large doses and no more. Ehrlich had pointed out the advantage of getting in the trypanocide when parasites were numerous in the blood. The theory was that some killed at once produced by their death antibodies, and to those the remainder succumbed. Tryparosan, introduced by Ehrlich, was a drug which promised to be of service. Broden and Rodhain tried it both intravenously and by mouth; the latter method was the more effective. Aniline antimonyl tartrate had been used with some apparent success by Thiroux, who found it more effective and less toxic than the potassium salt. None of the trypanocides at present in use could be relied on to banish the parasites from the cerebro-spinal fluid. Time had only emphasised the inefficacy of any treatment in advanced cases; life might be prolonged, but ultimate recovery could not be hoped for. They had now many years' experience of the disease in Europeans, and a study of the published cases led to the belief that recoveries almost certainly occurred, and, if the nature of the disease were recognised early enough, might be not infrequent. That opinion was shared by authorities such as Todd, Broden, and L. Martin and Darré. It was, of course, open to anyone to say now or five years hence that persons who had apparently recovered might relapse. When, however, they had a case such as that of the patient whose disease was diagnosed in 1903, and certainly existed in 1900, and who had now been in vigorous health for years, they were, he thought, justified in believing that the recovery was real. At present, unfortunately, they had no certain test of cure. Even susceptible animals might fail to be infected when trypanosomes were scarce. Of 30 Europeans who had died from the disease only two survived more than three years from the discovery of trypanosomes. That tended to show that patients who had survived more than three years, and were free from symptoms, had a chance of recovery. The human tissues tended to get the better of that as of all parasites. Five Europeans who had lived from 4¼ to 7½ years since trypanosomes were found in them were in June of this year in excellent health. As far as could be ascertained 3, 3½, 3½, 5½, and 7 years had passed since symptoms were observed. What share chemo-therapy had had in the restoration to health of those Europeans it was difficult to say; the treatment which many had was both short and simple. It was possible that their infections were mild and that they would have recovered without the use of drugs, never reaching the advanced stage. The broad principles of prophylaxis had been known since the discovery that glossina palpalis transmitted the disease. They consisted either in the removal of natives, infected or not infected, from the areas haunted by the fly, or in the destruction or banishment of the fly itself. Obviously the latter was the true prophylaxis, and if it should prove that wild animals harboured the virus, it was to measures directed against the fly that they must look more and more. The only certain way at present known of getting rid of tsetse flies was clearing—i.e., removing the vegetation which sheltered them and afforded opportunities for breeding. Recent work on drug prophylaxis suggested that some efficient preventive might be found in that direction. Morgenroth and Halberstaedter had been studying the action of quinine when injected into mice simultaneously with the virus of nagana. They found that when the mice were fed on quinine for a few days before the inoculation and the medication was continued afterwards no infection occurred. They had not yet found how long it was necessary to continue the quinine feeding. If the quinine was introduced under the skin it merely delayed the infection; if into the peritoneum it had no effect at all. The method should be tried with larger animals, for the mouse, owing partly to the large quantities of trypanocides it would bear, was the most easy of all mammals to treat. He was not aware of any attempts to administer trypanocidal drugs to monkeys and other susceptible animals while they were being subjected to the bites of infected flies. That surely was a promising line of research. In regard to South American trypanosomiasis, though the form of human trypanosomiasis discovered by Chagas in Brazil differed in many respects from the African disease, it deserved a short mention. It was briefly described in April of last year, but few details were available till the beginning of 1910. The parasite differed from that of sleeping sickness in two particulars; instead of multiplying by longitudinal fission in the peripheral blood it split up into eight merozoites within its limiting membrane in the lung capillaries, and, though that seemed less certain, it spent part of its life in the red corpuscle. In consequence of its mode of multiplication it had been named by Chagas schizotrypanum. The symptoms produced in man were similar to those of sleeping sickness, but there was no mention of lethargy or somnolence; the clinical records were at present scanty. The transmitting agent was a bug which sucked blood at night. It was the true host, for after feeding on an infected man or animal it was not capable of infecting another till eight days had passed, but after that remained infective for an indefinite period. Chagas believed that the forms which were to infect the new vertebrate left the alimentary canal and appeared in the body cavity, eventually reaching the salivary glands. At any rate, there seemed little doubt that trypanosome forms did appear in the body fluids. Chagas expressed the belief that only bugs which had flagellates in their salivary glands were infective, but he had brought no experimental proof; against that belief was the fact that he infected many animals by the introduction of fluid from the bug's intestine. From the result of his transmission experiments with different species of animals he concluded that the forms capable of infecting the bug developed only in certain animals; he instanced a South American monkey and man. He could not infect bugs from infected guinea-pigs. No observations besides those of Chagas had been published.

UNITED SERVICES MEDICAL SOCIETY.

Presidential Address.—Discussion on "Soldier's Heart."

A MEETING of this society was held at the Royal Army Medical College on Oct. 12th, Colonel Sir DAVID BRUCE, C.B., F.R.S., the President, being in the chair.

The PRESIDENT in addressing the members at the opening of the new session said: The subjects which may be brought before this society are, of course, very varied, including surgery, medicine, hygiene, organisation, and administration, on sea and land, during peace and war, at home and abroad, and it is therefore difficult, perhaps, to find a sufficient audience of medical officers interested in every paper which may be brought before this society. The other medical societies in London are more differentiated,

and therefore feel this difficulty less. But it must be borne in mind that it is not our business to become specialists to the exclusion of the other branches of our profession. We may be called upon at any moment to do the work of the oculist, laparotomist, bacteriologist, physicist, chemical analyst, &c., and in places where there are no experts to call in to our aid and often not even a book to consult. At the beginning of the siege of Ladysmith the first thing I was called on to do was to sew up several holes in a small intestine which had been wounded by an accidental revolver shot. When I look back on the same siege I see many things in the light of experience which could have been done better. For example, at that time we did not know so much about the breeding of flies as we do now. With our present knowledge I am sure we could have prevented to a great extent the truly Egyptian plague of flies which occurred and the consequent increase in the spread of enteric fever. In addition to being a surgeon and entomologist, it was very necessary to be a sanitary specialist, as the water-supply and the disposal of refuse in Ladysmith were also difficult to cope with. These arguments are brought forward to induce every naval, army, and territorial officer of the medical services within reach to attend our meetings. However interested they may be in some special subject, they will perhaps hear something, or see something demonstrated here, which will be of supreme advantage to them on some future occasion. Now what are the subjects which are most important at present to us as service men? In the front rank still stand enteric fever and dysentery. If anything could be done to enable the soldier to escape these diseases in time of war a very great advance would be made. In times of peace, in barracks and camps, doubtless the mode of fighting typhoid fever and dysentery by means of ordinary sanitary methods is the sound one. But on active service in the field it does not seem possible to keep them altogether in hand by these means, and some other method must be added. For my own part, I have always looked to some process of artificial immunisation as the most probable way to reach the wished-for result. If the soldier could be made completely immune to enteric fever and dysentery, even for only six months, the problem would be solved. Antityphoid inoculation was in vogue during the last South African war, but it proved useless. Since then the method has been improved by Leishmann, and the substantial lowering of the case-incidence is very gratifying, but whether this artificially induced immunity will stand the strain of active service remains to be proved. Malaria is another important malady affecting soldiers, and in spite of the epoch-making discoveries of Laveran and Ross little seems to be done in India and the colonies to prevent its ravages. Lately, it is true, a conference on malaria has been held at Simla, and something may now be done, but it is 30 years since Laveran discovered the cause of malaria, 12 since Ross discovered the mode of spread, and the same length of time since Koch demonstrated the use of quinine as a means of prevention. *Festina lente.* Plague is beginning to lose its terrors, as has been the case with cholera, now that its mode of conveyance by means of the rat-flea has been established and means of preventing it made possible. The work done under the direction of the Lister Institute by Lamb, Liston, and others of the Indian Medical Service is most illuminating and worthy of all praise. Sand-fly fever, although non-fatal and of short duration, also causes much sickness in many parts of the world, and has been the subject of investigation during the last two years by Birt and Marett. The interesting discovery that while in the larval stage the sand-fly depends for nourishment on the droppings of the wood-louse may open some way of prevention. The so-called seven-days' fever described by Rogers and Clayton is also of interest to the Navy and Army, but more work will require to be done before its true nature and mode of spread are established. In surgery there are numerous important questions, such as anæsthetics and antiseptics on active service, and many others. The effects of the spirochæta pallida and the gonococcus are still far too marked on our sailors and soldiers. A great deal could be done in the way of prevention if more determined efforts were made on the part of the military authorities and medical officers. The treatment of these diseases has progressed of late years, and there seems some likelihood of further improvement in this direction in the future. On the hygienic side of our work there are, of course, many of the most important subjects affecting the sailor and soldier. I have been struck lately by the discovery that beri-beri is due to the polishing of rice, by which it loses the greater part of its nourishing power. It might be worth investigating, if it has not already been done, as to how much of the nourishing power is taken from wheat by like processes. Then, again, there are questions of tinned foods and their effect on health. Why did so many of us suffer from jaundice in the South African war? How best to filter water in the field, the question of clothing, and the best mode of carrying kit, should the soldier's boot approach more to the natural shape of the human foot than it does now, or is the present shape satisfactory? The question of physical training of the soldier is also most important, and its effect on the soldier's heart. Medical organisation for war is completely altered. Questions coming under this heading are naturally of supreme importance to service officers. The Territorial Medical Force has been lately established in a much more serious fashion than the old Volunteer Force, and the organisation of voluntary aid societies has been put on a definite footing. We hope to have papers by Territorial officers on the special difficulties which affect their service. These and many other subjects ought to employ the energy and time of this society. Much has been done, but much more requires to be done. What is wanted is work, intelligent persevering work, as in my way of thinking Nature may be looked on as something ductile, which is capable of being moulded into any shape or form by the worker who is not discouraged by failure—

> "but strong in will
> To strive, to seek, to find,
> And not to yield."

Lieutenant-Colonel R. J. S. SIMPSON, C.M.G., R.A.M.C., and Dr. M. S. PEMBREY opened a discussion on "Soldier's Heart." Lieutenant-Colonel SIMPSON presented statistics which showed that the incidence of both valvular and functional disease of the heart attained its maximum in the third year of service, and that in spite of improvements in the physical training of soldiers the incidence was the same now as in 1890. The clinical features of disordered action of the heart were, in addition to increased rapidity in the pulse-rate, blue cold hands, defective muscular development, a low skin temperature, increase of the knee-jerks, and a generally increased muscular irritability. The blood pressure was high, ranging about 140 mm. Hg. As to treatment, he thought it a great mistake to put the patient to bed or to pay too much attention to the cardiac condition. At Woolwich they were kept employed in the garden, with great advantage; but he was of opinion that "disordered action of the heart" quite unfitted a man for soldiering. He suggested the possibility that the disease arose in persons with a congenital defect of their muscular system.—Dr. PEMBREY gave an outline of the mechanism regulating the heart beats. He agreed with Deane that there was no normal pulse-rate, but that each man had a pulse-rate peculiar to himself. The maximum incidence of cardiac disabilities in the third year of service showed that there must be something in a soldier's life which tended to the production of heart diseases. Soldiers at work were under a disadvantage as compared with civilians, since they worked heavily clothed and with a pack; the consequent rise of temperature and the dilatation of the cutaneous vessels threw a strain on the heart. Alcohol and smoking were factors common to civilians and soldiers, but he thought that those officers were right who did not permit smoking on the march. He suggested that the sharp tone in which orders were given might have an influence, since the necessary instantaneous response caused an increase in the pulse-rate; this had been shown by experiments on firemen. He agreed with Lieutenant-Colonel Simpson about the bad effects of bed on such cases, but did not agree that they should be invalided.—Dr. JAMES MACKENZIE asked whether men were admitted to hospital or rejected for service because they had a murmur or because they broke down. Many healthy hearts did show murmurs and he thought the rejection of recruits for a murmur alone was a mistake.—Surgeon-General A. M. BRANFOOT, C.I.E., I.M.S. (retired), attributed disordered action of the heart to cigarette smoking.—Dr. BYRES MOIR asked whether anyone had noted a connexion between tall men and disordered action of the heart. He thought small men were likely to make better soldiers, so far as the heart was concerned. An abnormally slow pulse was bad; such cases were

liable to syncope.—Lieutenant-Colonel H. E. DEANE, R.A.M.C. (retired), said he no longer believed that the position of attention had anything to do with soldier's heart nor over-training, since the men affected were soft, flabby men. Swedish exercises were no better than any other. He thought that clothing might have something to do with the causation.—Lieutenant-Colonel C. H. MELVILLE, R.A.M.C., suggested that the apparent increase in heart diseases in the third year of service might be attributed to the rejection of men coming up for foreign service. He attributed soldier's heart to the over-exercise of recruits before they were properly fed, and suggested that recruits should be fed up for a month before any serious work was given them. It was necessary to reject men with heart murmurs, since one could not separate injurious from harmless murmurs in a recruiting station.—Major W. S. HARRISON, R.A.M.C., referred to the work of Davy in 1876. Davy attributed soldier's heart to the compulsory position of "attention" which, as he pointed out, was accompanied by a habitual semi-expansion of the chest and loss of action of the respiratory pump. Lieutenant Hayes had done some experiments for Major Harrison, counting the pulses of men "standing easy" (in which position it was impossible to expand the chest in the soldier's habitual manner) and after five minutes' standing at "attention." In 29 observations there was an average increase of 7·5 beats in the pulse-rate after standing at "attention," the maximum increase being 20 beats, while in only 3 instances of the 29 was there no increase in the pulse-rate. Major Harrison also referred to a personal experiment, where he found that his pulse-rate was increased by 15 beats when he put on a tight jacket.—Fleet-Surgeon W. E. HOME, R N., thought that marines suffered more from heart troubles than bluejackets, and attributed the difference to the better feeding of the latter.—The PRESIDENT said that the diagnosis of valvular or functional disease of the heart in the Army was often a matter of personal equation in the observer. He related a personal observation when shooting on a very hot day; whilst he was wearing his coat he was much oppressed, but when he removed his coat he was able to shoot for the rest of the day in comfort. He suggested that the proper way to solve the etiological problem was by means of a series of well-conducted experiments.—Lieutenant-Colonel SIMPSON and Dr. PEMBREY then replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Liverpool on Oct. 21st, Dr. W. K. Walls, the President, being in the chair.—Dr. H. Leith Murray, Dr. R. Stenhouse Williams, and Dr. A. J. Wallace (Liverpool) communicated a paper on the Incidence, Characters, and Significance of Bacillus Coli in the Urine of Gynæcological Patients Before and After Operation. They found it present in 44·5 per cent. of normal urines examined before operation, and 93 per cent. after operation. The type in every instance was the B. coli verus of MacConkey, but agglutinative differences were readily made out. There appeared to be no relation between post-operative temperatures and the presence of the bacillus. The suggestion was made that, in inflammatory conditions, the bacillus in question may, more often than is thought, be a secondary infection.—Dr. Wallace showed an Unusual Specimen of great interest. The uterus was enlarged to the size of the six months gravid organ by the collection within it of several pints of dark, chocolate-coloured fluid. It was removed from a married woman, aged 67 years, who had passed the menopause 17 years previously. There was no new growth of the uterus to explain the condition. The history was of only three months' duration, and the signs and symptoms had led to the diagnosis of a malignant ovarian cystoma. Operation disclosed a dark-red, angry-looking uterine enlargement, which was thought to be due to a rapidly-growing sarcoma. Total hysterectomy was performed with fatal result (shock). The walls of the uterus were composed of fibro-muscular tissue, varying from three-eighths to one inch in thickness and without trace of lining endometrium or epithelium.—Mr. R. Favell (Sheffield) reported a case of Cæsarean Section for Concealed Accidental Hæmorrhage. The patient, a primigravida, aged 24, had been seized with acute abdominal pain and collapse the day before admission. She was seven months pregnant. On admission she was very pale and collapsed; pulse rate, 120; respirations, 40; marked œdema of the legs and face. The uterus was unduly enlarged, tense, and tender. The os was closed and the cervix not taken up. There was a little vaginal bleeding. There was only a drachm of urine in the bladder and that was loaded with albumin. Cæsarean section was at once performed. The uterine wall was of a mottled purple colour. More than two pounds of blood-clot was found in the uterus. The fœtus, well developed for seven months, was dead. There was no post-partum hæmorrhage. In spite of saline injections and other diuretic measures, anuria and uræmic coma ensued. Death occurred on the fourth day.—Dr. T. B. Grimsdale (Liverpool) recounted a case of Full-term Ectopic Pregnancy and showed the decomposing macerated fœtus which he had removed from the abdominal cavity. The patient, aged 24 years, had borne one child five years previously. There had been amenorrhœa for two years and an abdominal swelling for a few months less. Fifteen months previously she had had slight abdominal pain for two days; this was not accompanied by vaginal bleeding. Afterwards the abdominal swelling seemed to get smaller. Eight months later pain again occurred for a short time. For a month before admission to hospital she had had constant abdominal pain, and had been getting thinner and experiencing night sweats. Consideration of the history and the physical condition led to a correct diagnosis. The sac was intra-ligamentous; it contained a quantity of offensive gas as well as the stinking fœtus. The placenta was not seen. The sac was sutured to the abdominal wall and packed with gauze. Four months elapsed before it was closed and the wound healed.—Specimens were exhibited by Dr. D. Lloyd Roberts (Manchester), a Uterus showing Subserous Fibroids (calcified), Fibroid Polypus, and Cancer of Cervix; and by Dr. A. Donald (Manchester), (1) Infected Fibroid of Uterus; and (2) Cancer of Corpus Uteri.

Reviews and Notices of Books.

The Ear and Its Diseases. By ALBERT A. GRAY, M.D. Glasg. With stereoscope and 123 illustrations, of which 37 are stereoscopic. London: Baillière, Tindall, and Cox. 1910. Pp. 388. Price 12*s.* 6*d.* net.

COMING as it does from the pen of the scientific man whose researches upon the labyrinth have gained for him the blue ribbon of international otology, Dr. Gray's book naturally awakens many anticipations, and we may at once say that, in our opinion, these are favourably realised. Fertility of idea and suggestion combine with moderation and lucidity of expression to render the book one of the most important productions in recent otology. We are constrained to sound this high note of praise, not because we are at one with the author in all or most of his opinions, but chiefly because of the peculiarly stimulating quality of his writing.

Dr. Gray is well equipped for his task of expositor, and he does not spare pains. Upon the problems of acoustics and physiology he brings to bear a mind trained in the schools of physics and mathematics, while a wide clinical experience and lively critical acumen render his opinion upon such subjects as the indications for operation in aural suppuration worthy of the most weighty consideration.

The chapters upon anatomy and physiology are characterised by both depth and clearness. The researches and theories of the older workers are accurately, if briefly, detailed, and the results of the author's own investigations, many of which already occupy an honoured place in the history of otology, are imparted with becoming prudence and restraint. As illustrative of the suggestiveness of the comments in this section we may refer our readers to the remarks upon the powers of orientation manifested by certain animals, and upon the variable nature of sensory stimuli.

The section on general semeiology is remarkable for an effort to rehabilitate paracusis Willisii as a reliable guide to "the position and nature" of certain pathological conditions.

Whether or not this effort will succeed remains to be seen; but whatever the outcome may be, as a feat of speculative reasoning it certainly compels admiration. In this chapter also the author's theory upon the production of tinnitus is one which will create much interest even if it also may evoke some criticism. The pathogenesis of otosclerosis is another subject to which Dr. Gray has devoted much work and thought, and we believe that we express the general opinion when we say that at the present time his views hold the field to the exclusion of all others.

Apart from the author's views upon the vexed questions of otology—naturally the most attractive feature of his book to the philosophical mind—the volume will be found to be an eminently readable and practical guide to diseases of the ear, which we can confidently recommend to the beginner no less than to the expert. Our notice would be incomplete did we fail to call attention to the excellence of the illustrations.

Medical Supervision in Schools. By EDWARD M. STEVEN, M.B., Ch.M. Edin., Royal Commissioner for South Australia, 1909. London: Baillière, Tindall, and Cox. Pp. 268. Price 5*s.* net.

Dr. Steven's book represents a part of the result of his tour in Great Britain, Canada, the United States, Germany, and Switzerland as commissioner to inquire into medical inspection and allied subjects on behalf of the Government of South Australia. The volume describes the special systems in force and the special methods used in Great Britain, on the Continent, and in America, and will be useful as enabling the school doctor in one place to compare the detail of his procedure with that of a colleague on the other side of the globe. These comparisons cannot fail to be fruitful, and are made much more vivid by the provision of some 40 good photographic illustrations of all kinds of details—from school nursing to school baths—in various parts of the world. Dr. Steven's method brings out some piquant divergences of opinion, as when he quotes the diatribe of Dr. Sheard of Toronto against medical inspection of school children, which is described "as a pure fad, instituted principally by women and agitators ..... who desire easy billets for their friends, with good pay and little work." Dr. Sheard can hardly be dealing with conditions analogous to those existent in other and larger urban centres, and it is conceivable that he does not know what all those conditions are.

There are also interesting divergences of fact in the various chapters which make suggestive reading. Thus it is known that the percentage of phthisis among London school children is very low, whereas Dr. Steven informs us, from the information he has collected, that in New York "cases of incipient phthisis are innumerable." This applies apparently chiefly to the Italian population. An isolated observation made in this section is also of some interest; it is a note on "the lack of care exercised by the average American general practitioner in regard to his personal appearance. It is no uncommon circumstance to meet the average school medical officer in no better habiliment than a third-rate London clerk." Dr. Steven mentions also a beard "of three days' growth, greasy clothes, and sometimes a quid of tobacco in his cheek." Fortunately, this observation (which might perhaps have been made in other countries also) does not prevent Dr. Steven saying of medical inspection in New York that "the authorities can well command the admiration and esteem of all nations throughout the civilised world for their honesty of purpose," and "their extreme desire and unswerving endeavour to protect their children." It is unfortunate that this does not prevent the terrible overcrowding in the tenements and the high rate of incidence and mortality of phthisis, matters upon which we have commented recently in THE LANCET.

One of the most interesting sections of the book is that dealing with Germany and Switzerland. Here we are told the details of examination and treatment in Cologne, Charlottenburg, Munich, Frankfort on the Main, Wiesbaden, Strasburg, and Zürich. It is with regard to treatment in the special school clinics that German experience is particularly valuable just now, and the detailed descriptions of the dental clinics at Strasburg and at Cologne are very useful for comparative purposes. Dental clinics also exist at Wiesbaden and Zürich. At Wiesbaden the question of the treatment of school children, apart from teeth, has been temporarily solved by the establishment of a voluntary clinic by six consultants who give their services free, the rent of the building being paid by the town.

Zürich devotes a good deal of attention to stutterers and issues long printed instructions for use at home and for treatment at school. To Charlottenburg belongs the honour of having established the first "open-air school" (although the medical officer, Dr. Neufert, prefers to call it "forest school"), and the seventeenth chapter contains a useful description of the buildings and organisation. In one matter Germany is notably in advance of this country and that is in the provision of school baths. Dr. Steven sums up his impressions of this detail of school life in his penultimate chapter and gives some good diagrams and sketches of baths in Wiesbaden, Frankfort, Munich, and Cologne.

We are so much in the habit of hearing of the German superiority in school matters that it is rather remarkable to learn from Dr. Steven of the impression made upon him by the poverty of Germany. Dr. Steven says it "must be distinctly understood that the latter [Wiesbaden] is by no means the only place in Germany where this is particularly noticeable," and goes on: "Much more distress, in the shape of abject poverty, as evinced by the pinched faces, eager, hungry expressions, and sparkling eyes, exists in enlightened Germany than in most civilised countries." The observation suggests itself that it may have been the existence of this urgent poverty which quickened and stimulated the application of medical inspection and medical treatment in Germany.

Dr. Steven's book may be recommended to the school doctor and the educationist as an interesting and useful record of the actual organisation and methods in use in the different places described, and will serve a good purpose as a source from which further suggestions for organisation may be drawn.

Die Operative Geburtshilfe der Praxis und Klinik. (*The Operative Midwifery of Practice and of the Clinique.*) Von Dr. HERMANN FEHLING, Ord. Professor der Geburtshilfe und Gynaekologie zu Strassburg. With 77 illustrations. Wiesbaden: J. F. Bergmann. 1909. Pp. 190. Price 4*s.*

THE object of this work is to afford the general practitioner a *résumé* of the advances which have been made of recent years in the practice of operative midwifery. As Professor Fehling points out, the busy practitioner has neither the time nor the knowledge needed to enable him to determine what is good and what is bad practice with regard to the new methods which are introduced from time to time, and it is most important that he should recognise clearly the class of operation which he is justified in undertaking himself and that for which the patient should be entrusted to the care of a specialist or sent into a properly equipped hospital or home.

The book is concerned solely with the various operative procedures of midwifery and is divided into some 20 sections. In the description of the extraction of the after-coming head in a flattened pelvis the author recommends in cases of difficulty the use of Walcher's position.

The illustration, however, in which the two assistants are holding the legs of the patient, hardly gives a true representation of this position, since it is essential that the patient's legs should be allowed to hang freely if any real increase in the conjugate diameter is to be obtained. In a later chapter a more correct drawing of the proper attitude is given, with the patient represented as hanging with the legs free over the end of a special elevated plane. The question as to the correct foot to seize in the performance of internal version is always a matter upon which there may be a legitimate difference of opinion, but we think that in the figure given of internal version with a dorso-anterior position of the shoulder the representation of the introduction of the right hand, the patient lying on her back, is a mistake, and the use of the left hand with its palmar aspect corresponding to the abdomen of the child would be more convenient and more correct. It is interesting to note that while Sir James Simpson taught that it was best to seize the leg of the opposite side of the body to the presenting shoulder, most foreign obstetricians rightly recommend seizing the lower leg—namely, that corresponding to the presenting shoulder. That this is the correct method of performing version as well as the easiest has been demonstrated conclusively by Galabin, who has pointed out that the force applied to the lower leg acts at a greater mechanical advantage, producing rotation in one plane, than traction applied to the upper leg, which produces a combined rotation of the trunk of the fœtus about a transverse and a longitudinal axis, so as to bring into the os the opposite pole to the shoulder originally presenting.

The figure of Tarnier's forceps given is that of a very poor pattern of axis-traction forceps, a matter in which the English school of obstetricians appears to have a distinct advantage over most others if we may judge by the axis-traction forceps figured in many foreign text-books of midwifery. We notice, too, that the author apparently recommends a very inferior pattern of Levret's perforator, and, like most German obstetricians, prefers the blunt hook for decapitation, a preference which personally we can never understand, converting, as it does, a comparatively easy operation into a difficult one. The treatment of cases of ruptured uterus is another matter upon which there are many differences of opinion, but we are surprised to find Professor Fehling recommending that in cases of rupture where the child has escaped partly into the abdomen, it should be extracted if possible through the rent by the feet rather than that abdominal section should be performed.

The book will prove useful, no doubt, to those for whom it is written.

Surgical Diagnosis. By EDWARD MARTIN, M.D., Professor of Clinical Surgery in the University of Pennsylvania. Illustrated with 445 engravings and 18 plates in colours and monochrome. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1910. Pp. 772. Price 28*s.* net.

ON the accuracy of the diagnosis depends mainly the success of the treatment, and it is in diagnosis that more mistakes are made than in treatment itself. It is, however, far easier to teach the student the correct treatment to be adopted for various conditions than it is to make him capable of distinguishing those conditions each from the other. It is only in the out-patient room and in the wards that diagnosis can really be learned, but great assistance can be rendered to the student by suitable books. It is not possible by books alone to teach diagnosis, but judiciously used books are of real value, for they will remind the student in what direction he should search for symptoms or signs, and they will enable him to estimate the relative value of the various indications supplied by the case.

The first chapter on the laboratory diagnosis has been written by Dr. W. T. Longcope, and it is useful so far as it goes, but considering the important position that has now been assumed by laboratory methods of diagnosis, we consider that fuller treatment would have been of greater value. It is of little use merely to say, "To estimate the coagulation power of the blood Wright's tubes may be used, but the new instrument devised by Boggs is much simpler in application and probably more accurate," without a word as to the nature of these instruments. We may, however, refer with approval to the excellent plates which illustrate this chapter. Dr. H. K. Pancoast has supplied a useful, if brief, chapter on the applications of the X rays to surgical diagnosis.

In succeeding chapters various systems of the body are taken in order, such as the bones, the joints, and the bursæ, and their most common lesions are briefly referred to. A chapter then follows on diseases of the nervous system written by Dr. T. H. Weisenburg. This is illustrated by some useful plates showing the innervation of the skin and the relation of various nerve trunks to the spinal nerves. The diagnosis of injuries and diseases of the nervous system, always so puzzling to even experienced observers, is here made fairly simple, and the teaching of the book should be of real service in clinical work. The other chapters deal with various regions of the body: one treats of the head, face, and neck; another of the spinal column, and so on.

The whole book is very extensively illustrated, the majority of the illustrations being reproduced from photographs of typical lesions. Although theoretically a reproduction from a photograph is more likely to give an accurate representation of the condition present, it must not be forgotten that the lighting of many photographs is inexpertly managed, with the result that a photographic reproduction such as that of a goitre on p. 328 may be practically of no value, for it is impossible to see that any swelling is present. But the outline drawings illustrating the injuries to the bones in the neighbourhood of the joints are excellent.

When the difficulty of writing a book of diagnosis is considered, we think it may be said that Professor Martin and his coadjutors have attained a high degree of success in their endeavour. Used sensibly the manual will afford the student much assistance in diagnosis.

Lehrbuch der Speziellen Pathologischen Anatomie für Studierende und Aerzte. (*Text-book of Special Pathological Anatomy for Students and Practitioners.*) Von Dr. EDUARD KAUFMANN, Ord. Professor der Allgemeinen Pathologie, und Pathologischen Anatomie; Direktor des Pathologischen Instituts der Universität Göttingen. Fifth revised and enlarged edition. With 686 illustrations. Berlin: Georg Reimer. 1909. Pp. 1383. Price, paper cover, M. 23; bound, M. 25.50.

THE appearance of a fifth edition of Professor Kaufmann's text-book is good evidence of its popularity in his own country, and from our examination of its scope and nature it deserves the reputation it has achieved. It gives an exhaustive account of the morbid conditions met with in the various systems and organs of the body, including their macroscopic and microscopic appearances, so that it is more than a mere catalogue of morbid anatomical changes in the organs. To each section is prefixed a brief description of the anatomy and development of the organ with which it is concerned. The various malformations, inflammatory changes, new growths, parasites, and other abnormalities are then described at some length, and, where necessary, the pathogenesis of these conditions is discussed and any theories offered in explanation are given. The book is copiously illustrated by figures demonstrating the gross and microscopical changes described. The subject-matter is well arranged, and various different-sized types are used, thus facilitating reference. The illustrations are in many cases less elaborate, and often more diagrammatic, than is

now the vogue in English text-books on pathology, but they are explicit and are sufficiently clear to be useful. Apart from the authorities quoted in the text, and Professor Kaufmann is scrupulous in giving the names of those whose views he refers to, there is a bibliography at the end of the book extending to 75 closely printed pages. The only criticism we have to offer is that the work of English pathologists receives but little notice, though this is a not uncommon occurrence in German text-books. Professor Kaufmann's book is a valuable work of reference, especially as representative of German pathology.

LIBRARY TABLE.

The Rearing of Children. A Practical Handbook for Mothers. By J. P. O'HEA, M.B. Lond., F.R.C.S. Eng. London: The Scientific Press, Limited. Pp. 175. Price 2*s.* net. *A Manual of Nursery Hygiene.* By W. M. FELDMAN, M.R.C.S. Eng., L.R.C.P. Lond., Lecturer on Midwifery, Hygiene, Infant Care, Nursing, &c., to the London County Council. London: Baillière, Tindall, and Cox. 1910. Pp. 168. Price 2*s.* 6*d.* net.—The increasing interest taken in the study of infancy and childhood is evidenced by the number of books devoted to supplying information in regard to the care of the young. There are many matters in which it is highly desirable that those having charge of children should be educated in order to avoid the numerous preventable diseases and disorders to which the young are so liable. In regard to the feeding, clothing, and general management of infants and children there is still a lamentable ignorance among many persons. Dr. O'Hea's little book supplies in small compass and in simple yet readable language information which is calculated to enable mothers to do the best for their offspring. The first section is devoted to the feeding of infants, and the directions given are sound and in accordance with the generally accepted principles of infant feeding. The rules for breast feeding are set forth, and full directions are given for artificial feeding when for any reason suckling by the mother is impracticable. The second section gives some general information about the ordinary infectious diseases, with directions for the management of children affected by them. The third and fourth sections deal with rickets and some of the common ailments of childhood. Useful hints in regard to breathing exercises are also given. The book is characterised by the sound common sense of its recommendations.——Mr. Feldman states in his preface that his book is intended for mothers of the so-called middle classes and for district nurses and health visitors. It also contains a large amount of valuable information concerning the care and management of infants and children in health and in illness. Questions of clothing, feeding, and of the general hygiene of the nursery are dealt with scientifically and in accordance with sound common-sense principles; moreover, wherever possible, the reasons for the recommendations offered are given. There are chapters on the use and abuse of patent or proprietary foods, on ailments due to improper feeding, and on the nature, prevention, and treatment of rickets. Simple directions for the management of infants in convulsions are also given, and some general information on the infectious diseases, on tuberculous disease, and on some common ailments is afforded. An interesting chapter is devoted to vaccination, and in it the fallacies of the antivaccinationists are exposed. The second part of the book is concerned with the health of the mother. It gives some useful information regarding the hygiene of pregnancy and the periods of lying-in and lactation. This little book should be useful in diffusing important information to mothers and others concerned in the management of children. We can cordially commend it for this purpose.

A Manual of Normal Histology and Organography. By CHARLES HILL, Ph.D., M.D., formerly Assistant Professor of Histology and Embryology at the Northwestern University Medical School, Chicago. Second edition. London and Philadelphia: W. B. Saunders Co. 1909. Pp. 468. Price 10*s.* net.—We have little to add to the remarks which we made on the first edition of this manual. To deal with the whole subject of the gross and microscopical anatomy of the organs of the human body in a volume of this size necessitates considerable compression. This is carried so far that the book would not constitute a sufficient text-book for students, in this country at all events. Its strong point is its illustrations, which are numerous, and for the most part good. As a supplement to lectures on histology, or as a means of rapidly looking through the subject dealt with by a lecturer, it has merits. The attention devoted to the teeth should render it acceptable to dental students. There are brief notes on preparation of material in the introductory section and on laboratory methods and formulæ at the end. It is not very clear why these should not have been combined in one chapter. The print and paper are good, and the price is moderate for an American book.

Francis Bacon: a Sketch of his Life, Works, and Literary Friends; chiefly from a Bibliographical Point of View. By G. WALTER STEEVES, M.D. Brux. London: Methuen and Co. 1910. Pp. 230. Price 6*s.* net.—This modest volume makes no attempt to give any fresh details of Bacon's life, and it adds little that is new to the list of his works. As the expanded title indicates, it consists of a short historical summary of the great philosopher's writings. Though this summary is to some extent chronological, Dr. Steeves has classified Bacon's works into three main headings: (1) philosophical; (2) literary; and (3) professional, or legal. So little is attempted in the way of synopsis or criticism of the material, that the purely literary output of Bacon's pen occupies far the largest part of these divisions, and even readers well versed in Bacon will find their attention drawn to rare fragments of considerable value. As an instance, the tract on "The Character of a Believing Christian in Paradoxes and Seeming Contradictions" is accepted as genuine by Dr. Steeves, and his judgment in the acceptance is probably correct. It certainly forms a valuable addendum to Bacon's "Confession of Faith," though it is not mentioned either by Rawley or Tenison. To those who know little of Bacon's writings this volume will be a good guide with which to start, while the copious details of minor works will make it indispensable to the real scholar of Baconian wisdom. The book is studded with facsimiles of various title pages, which are interesting, but are inserted in such a haphazard way that they start out of the pages like electric advertisements of whisky or meat extracts in the streets of London.

The Abuse of the Singing and Speaking Voice: Causes, Effects, and Treatment. By E. J. MOURE and A. BOUYER, Fils. Translated by MACLEOD YEARSLEY, F.R.C.S. Eng. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1910. Pp. 130. Price 12*s.* 6*d.* net.—The appearance in English of Moure and Bouyer's manual on the abuse of the voice is very welcome. The book is one which should be read not only by every teacher of singing but by laryngologists. The faulty technique so prevalent to-day, which, as every throat surgeon knows, often ends in irreparable damage to the vocal organs, is, we are told, dependent upon three factors: first, the failure on the part of teachers to recognise and to allow for physical disproportion, when it exists, between the several

parts of the voice-producing mechanism—lungs, larynx, and upper air-passages; secondly, the practice of habitually forcing the voice to its extremes of power and compass; and thirdly, the too frequent use of the "chest register." In the way of treatment more can be got from preventive than curative measures. Consequently, it is advised that both at the outset of his training and during its progress the student should be placed under the surveillance of the laryngologist working in coöperation with the teacher. In these and many other important matters the book marks a new departure, and if its injunctions can be carried into effect it may herald a brighter era for vocalists. The translation is careful and exact, but shows some tendency to adhere too rigidly to the French idiom.

Manual of Medical Jurisprudence, Toxicology, and Public Health. By W. G. AITCHISON ROBERTSON, M.D., D.Sc. Edin., F.R.C.P. Edin., F.R.S. Edin. Second edition. Edinburgh: John Currie. 1910. Pp. 560. Price 8*s*.—In THE LANCET of Sept. 5th, 1908, we reviewed the first edition of this work and explained its nature and scope. We considered that it contained all that was necessary for the student to know in regard to medical jurisprudence, toxicology, and public health for the ordinary pass examinations in the final subjects, but for the higher examinations a larger work would be necessary. We now have to repeat that opinion, for the author states in his preface that as so short a period has elapsed since the appearance of the first edition, few changes have been rendered necessary. The passing of the Poisons and Pharmacy Act, 1908, receives brief consideration, as does the Children Act of the same year. A short description has been added as to the mechanical filtration of water, taking note of the many processes which have been patented for purifying water on a large scale by mechanical means. It is affirmed that by such methods the water is filtered more quickly than, and quite as thoroughly as in the filter-bed, that it is continuously efficient, that it costs much less to install, and "almost nothing to keep up, while a very small area of ground suffices." A very short account is given of Bell's patent process and of the "Candy filters," but no comment is made on their efficacy or practicability.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLI., Nos. 1 and 2. London: C. F. Clay, Cambridge University Press. Oct. 11th, 1910.—The present part contains: 1. A Reversed Action of the Vagus on the Mammalian Heart, by H. H. Dale, P. P. Laidlaw, and C. T. Symons. The well-known phenomenon is best exhibited in the cat, and with the use of paraldehyde as an anæsthetic, after the previous action of chloroform or ether, either vagus produces it equally well. It is exhibited also with tropine in from 50 to 150 milligramme doses injected intravenously, and with nicotine in 1 to 2 milligramme doses. Hordenine methiodide may be substituted and curare also. Many text figures show the effects of the vagus stimulation when the animals have been subjected to these drugs. The authors of the article think that the effects are due to the presence in the vagus of normally masked accelerator fibres. 2. Chemical Structure and Sympathomimetic Action of Amines, by G. Barger and H. H. Dale, from the Wellcome Physiological Research Laboratories. The chemical side of this investigation is due to Mr. Barger and Mr. A. J. Ewins, whilst Mr. H. H. Dale is responsible for the physiological experiments. The importance of the ketones and of the corresponding secondary alcohols in causing and intensifying the adrenin-like action in blood pressure has been shown by various observers, and it was supposed by Dakin that this effect was due to the catechol nucleus, but evidence is here given that certain amines produced by putrefaction, none of which have a catechol nucleus, have a similar action to adrenin. Hence the conception is inadequate. The authors, therefore, proposed to trace the variations in the intensity of the specific action through a series of compounds intermediate between the putrefactive amines, in particular *p*-hydroxyphenylethylamine, and adrenin itself. These compounds simulate the effects of sympathetic nerve stimulation on muscle cells and gland cells. Hence, instead of terming the action of such bases "adrenin-like" they propose to substitute the term "sympatho-mimetic." The rest of the article is devoted to the action of the various amines, with many woodcuts exhibiting their effects. Catechol, they find, has no sympatho-mimetic action. 3. The Gases of the Arterial and Venous Blood of the Cat, by George A. Buckmaster and J. A. Gardner, from the Physiological Laboratory, University of London. 4. An Investigation of the Sino-auricular Node of the Mammalian Heart, by Martin Flack. 5. The Fate of Parahydroxyphenylethylamine, by A. J. Ewins and P. P. Laidlaw, from the Wellcome Laboratories. 6. On the Production of Glycosuria in Relation to the Activity of the Pancreas, by Ivor Ll. Tuckett, M.A., M.D.

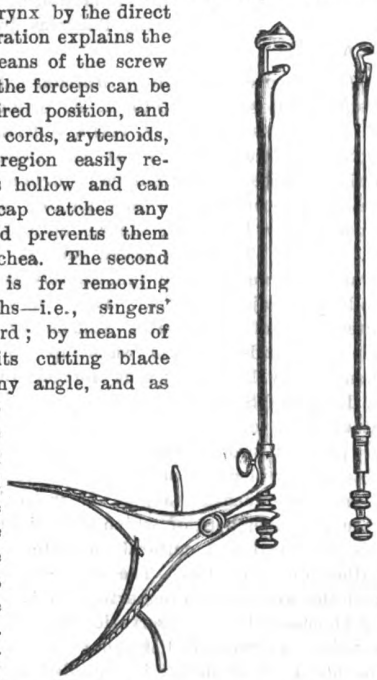
The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. IV., No. 13. October, 1910. Oxford: At the Clarendon Press. Subscription price, 25*s*. per annum; single numbers, 8*s*. 6*d*. each net.—The contents of this number are: 1. The Pulse Immediately Preceding the Epileptic Attack, by Alexander G. Gibson, T. Saxty Good, and R. Greenwood Penny. Tracings were obtained immediately before the fit in five epileptic major attacks. They show that there is no alteration of the pulse sufficiently definite to affect the amplitude of the wave up to the point where clonic convulsions prevent further record being taken. 2. Influenzal Septicæmia, with a Short Review of the Present Status of Bacillus Influenzæ, by Hugh Thursfield. Details are given of two cases from which the bacillus influenzæ was obtained by blood culture. Dr. Thursfield suggests that the so-called influenza bacillus is in reality only one of a group, the members of which show similar, if not identical, morphological and cultural characters but possess different pathogenic properties. The suggestive contribution is dealt with this week in a leading article. 3. Hereditary Hæmophilia, by Thomas Addis. Observations upon 12 cases are recorded showing a marked deficiency in the coagulability of the blood. This defect is regarded as the only immediate cause of the condition. 4. A Further Note on Hæmatoporphyrinuria not due to Sulphonal, by T. K. Monro. 5. Two Cases of Acute Endocarditis, by John Cowan, A. M. Kennedy, A. R. Patterson, and John H. Teacher. An interesting clinical and pathological study of the heart in two fatal cases of endocarditis is given. Microscopical examination of the *a.v.* node and bundle revealed well-marked inflammatory lesions which are regarded as explaining certain alterations in the *a.c.* interval of the jugular pulse curves. 6. Tuberous (Tuberose) Sclerosis, by J. S. Fowler and W. E. Carnegie Dickson. A case is recorded and an analysis is given of the literature of the subject. The writers conclude that tuberous sclerosis constitutes a definite form of idiocy, and that it may sometimes be diagnosed during life by the recognition of some of the associated tumours in a mentally defective person who is, or has been, subject to epileptiform convulsions. 7. Coupled Rhythms of the Heart, by John M. Cowan and W. T. Ritchie. They prefer the term coupled rhythm for the conditions described to that of pulsus bigeminus, and they do not include the pulsus alternans. They divide the cases into

two groups—those of the ventricles alone and those of both auricles and ventricles. Coupled rhythms may occur from various causes and are often due to a regularly recurring extra-systole, most frequently of ventricular origin. The writers of the paper sum up their views in the following sentence: "Whenever an enfeebled heart is unduly irritable in an abnormal site, any excessive rise of intracardiac pressure may produce a regularly recurring premature systole which originates in the irritable area." 8. The Outlook of Sufferers from Exophthalmic Goitre, by W. Hale White. The after-histories of a considerable number of hospital and private cases are given, with a view to throwing light upon the outlook of patients with this disease apart from operative measures.

New Inventions.

IMPROVED LARYNGEAL FORCEPS.

Messrs. Krohne and Sesemann have recently made this instrument for me, and I have found it very useful for operations on the larynx by the direct method. The illustration explains the mechanism. By means of the screw the cutting part of the forceps can be rotated to the required position, and the growths on the cords, arytenoids, or inter-arytenoid region easily removed. The cap is hollow and can be opened; this cap catches any pieces removed and prevents them passing into the trachea. The second attachment shown is for removing very small growths—i.e., singers' nodes from the cord; by means of the same screw its cutting blade can be fixed at any angle, and as the blade fits into a depression on the foot-piece which is under the cord the growths can be removed and the risk of injuring the cord is reduced to a minimum. The different attachments can easily be removed from the handle.



GEORGE N. BIGGS, M.B., B.S. Durh.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

A COUNCIL meeting of this association was held at 34, Copthall-avenue, London, E.C., on Oct. 18th. Mr. D. B. BALDING was in the chair.

A letter was considered from a country member complaining that the guardians in his district had appointed as district medical officer a practitioner who resided seven miles away from his district. This had been sanctioned for one year by the Local Government Board, but recently he had been re-elected by the guardians for a further period of three years. It was unanimously considered by the council that the matter required investigation; that on the face of it it was a scandal to appoint a district medical officer living seven miles away from his district, having regard to the necessities of the sick poor.

A communication was received from a public vaccinator complaining that because he had resigned his district medical officership on account of inadequate remuneration he was now threatened with the loss of his vaccination office. The local division of the British Medical Association had banned the appointment he had resigned, and so far there had been no applicants, but he felt sure that if no one would take this post at the old rate the guardians would endeavour to attract applicants by adding the post of public vaccinator to it. Strong comments were made by those present on the unprotected position of the public vaccinator, and the unscrupulous use made by the guardians of the remuneration from this source to underpay Poor-law appointments. It was regretted by the council that no assistance could be given to their correspondent. Under the present law only a month's notice need be given by the guardians to determine any public vaccinator's office, and this could be done without any reason being given, and it appeared that the Local Government Board had no control in the matter at all.

Another correspondent wrote complaining of the refusal of his guardians to allow him the extra fee of £2 for attendance on a long case of phlegmasia dolens on the ground that he had not attended at the confinement of the patient, having only received the order 12 days afterwards. He quoted from Art. 182 of the Gen. Ord. of July, 1847, which lays down that a district medical officer shall be entitled to a fee of £2 in any "special case where great difficulty may have occurred in the delivery, *or long subsequent attendance in respect of some puerperal malady, or affection, may have been requisite.*" There was some difference of opinion on this point. It was thought by some that in order to be entitled to this fee the medical officer must have been called to the confinement or very shortly afterwards. But a majority of the council thought that under the article any long-continued attendance on a puerperal case was sufficient, and the honorary secretary was instructed to write and advise the member to push his claim and proffer the assistance of the association.

A delegate from the district medical officers of a metropolitan borough also attended the council meeting to ask for assistance. He stated that the guardians, owing to a recent resignation of one of the district medical officers, were endeavouring to reduce the number of district medical officers from five to four and to force on to two of their number the vacated district under very inequitable conditions. The district medical officers claimed that there should be a re-arrangement of the whole area. That under the present arrangement only one of their number received about the average payment of the district medical officers throughout the metropolitan district—viz., 3*s.* per order. That all the others were being paid less than 2*s.* per order. They had sent in a memorial to their board of guardians, and if this were ignored they proposed to carry it to the Local Government Board. The council expressed its sympathy and promised all the assistance in its power.

The honorary secretary read a letter from Mr. Shirley Fussell asking the association to appoint four delegates to meet delegates from the National Poor Law Officers' Association, the Union and Rural District Clerks' Association, and the Workhouse Masters' and Matrons' Association in a joint conference to consider the recommendations of the Royal Commission on the Poor-laws affecting the interests of Poor-law officers, and report as to what action (if any) it is necessary or desirable to take now, or in the future, to safeguard the interests of the service.

The council appointed Mr. W. Holder (Hull), Mr. A. A. Napper (Cranleigh), Dr. F. S. Toogood (London), and Dr. Major Greenwood (London) to represent the Poor-law Medical Officers' Association in the proposed conference.

CONTINENTAL ANGLO-AMERICAN MEDICAL SOCIETY.—The annual meeting of this society was held at 81, Boulevard Malesherbes, Paris, on Oct. 15th. The annual dinner was held in the evening at the Carlton Hotel, Paris. The chair was occupied by Sir Frederick Treves, who warmly congratulated the society on its excellent work, laying stress on its usefulness in uniting and in bringing to the notice of the profession at home responsible men to whom patients travelling abroad could be safely entrusted. This very successful gathering was brought to a close by two happy speeches from Professor Tuffier of Paris and Dr. Alexander Lambert of New York, who assured the members of the regard of their colleagues in France and in America.

THE LANCET.

LONDON: SATURDAY, OCTOBER 29, 1910.

Report on the Measures Taken Against Malaria in the Lahore (Mian Mir) Cantonment.

THERE was a considerable conflict of opinion respecting the value of the results obtained at Mian Mir from the experiment, begun in 1901, of applying anti-mosquito measures for the prevention of malaria at that station. By some the experiment was regarded as a failure, although every chance had been given to it; by others it was contended that it would have been a success if the programme had been fully followed up. In consequence of the controversy Mian Mir acquired considerable notoriety, which may have led the authorities recently to change the name to "Lahore Cantonment." As the results of the anti-mosquito campaign remained in doubt, suggestion was made that the Indian Government should institute an impartial inquiry into the Mian Mir experiment. Accordingly they appointed a commission in October last to make the necessary investigation. The commissioners were three in number—viz., the Hon. R. NATHAN, C.I.E., of the Indian Civil Service; Lieutenant-Colonel H. B. THORNHILL, C.I.E., of the Indian Army; and Major L. ROGERS, M.D. Lond., I.M.S., Professor of Pathology in the Calcutta Medical College, only the last of them, therefore, being a medical man, but he a well-known authority on fevers of the tropics.

The terms of reference to this small but well-equipped commission were "to inquire and report upon (1) the manner in which the Mian Mir experiments, which had for their object the extermination of mosquitoes and the abolition of malaria by means of operations against mosquitoes, were carried out; (2) the results obtained from the operations at Mian Mir; and (3) whether operations similar to those employed at Ismailia, Panama, and Lagos can be successfully applied to Indian centres of population." The commissioners visited Lahore cantonment on Oct. 21st and spent six days in making a general survey of the station, examining the drainage system, inspecting the excavations and depressions likely to serve as breeding places for anopheles, searching for adult malaria-bearing mosquitoes, examining the spleens of children in the native bazaars, and testing their blood infection. Statistics and other data were also collected, and evidence was taken on the spot from a number of witnesses resident in the cantonment. On their return to Simla the commissioners examined other witnesses; in all some 22 persons gave evidence, 13 of them being medical men. On their visit to Mian Mir the commissioners were accompanied by Captain S. R. CHRISTOPHERS, I.M.S., who had taken part in carrying out the original anti-mosquito campaign which was begun in 1901. The report of the commission, which is dated Nov. 25th, 1909, was completed with great promptitude, for the interval between the beginning of the inquiry and the report was little over a month. The report is made under five chief headings which relate to (1) description of the cantonment; (2) an account of the operations carried out by Major JAMES and Captain CHRISTOPHERS during 1901–3, and their results; (3) an account of the general operations undertaken by the military authorities from 1904–09; (4) the result of these measures; and (5) an examination of anti-malarial campaigns in other countries with a view to test the applicability of similar measures to Indian conditions. The report comprises some 60 folio pages of printed matter, including tables of statistics. In addition there are two maps and a number of charts. In their summary of conclusions the commissioners say that while anti-malarial operations in Mian Mir were carried out under conditions which were in many respects favourable, yet, on the other hand, there were circumstances which undoubtedly interfered with the success of the experiment. Among these it may be mentioned that the station as well as the surrounding country is flat, the subsoil when wetted becomes impervious, the rainfall is concentrated into the autumn months, and its distribution in some years is favourable to the breeding of anopheles. Moreover, the cantonment is very large (8 square miles) compared with its population (16,000), and its drainage system involves the maintenance of an enormous length of earth drains. A whole series of deep excavations and other depressions lie immediately around the station. Lastly, the native bazaars, lines, and servants' quarters with infected children are interspersed throughout the cantonment with bodies of troops, including non-immune Europeans. As regards the later stage of the anti-mosquito campaign, the commissioners say that the special facilities offered by the military organisation and strength of the station were utilised to the utmost extent, and an immense amount of work was done to abolish the breeding-places of anopheles within the cantonment. The closing of the irrigation channels, the reform of the drainage, and the filling up of depressions during the period 1904 to 1909 must have had an enormous effect in diminishing the opportunities for the breeding of mosquitoes. The commissioners, in fact, assert that it would not be easy to find elsewhere an example of equally thorough and painstaking operations. Notwithstanding all that was done, the mosquito breeding-places were not altogether abolished. Minor anti-larval operations in all parts of the cantonment and in all seasons had not been adequate to suppress completely the breeding of mosquitoes where opportunity for this still existed. The effect of the measures on the malarial conditions of the station appeared to the commissioners to be negative. Adult anopheles, it is said, were as abundant as ever and malaria was no less prevalent than before among the native population. Making allowances for causes affecting statistics, there would seem to be some, though perhaps not very great, diminution of malaria among the British troops. Having regard (1) to the similar reductions in other cantonments, (2) to the degree of perfection with which quinine prophylaxis is now carried out, and (3) to the fact that any improvement that there may be would not appear to be shared by a native population among whom quinine prophylaxis is imperfect or non-existent, the commissioners do not think that there is

any proof that the anti-larval operations have contributed materially to the diminution.

The whole situation illustrates the difficulties of eradicating mosquitoes, and emphasises, in the opinion of the commissioners, the need for further research and experiment. In accounting for this failure two conjectures are hazarded in the report: either (1) the circumstance that a very great but not altogether perfect reduction of breeding-places does not appear to have been accompanied by an improvement of malarial conditions may possibly indicate that where other conditions favour the existence of malaria partial abolition is of no avail until a point is reached nearer total abolition than has hitherto been anticipated; or (2) the existence of an enormous collection of breeding places situated all around the station, but at some distance from it, may enable mosquitoes breeding in those places to frequent the lines and the bazaars for their food in such numbers as to neutralise the effect of diminished breeding within the inhabited area. If this be the case it follows that protective measures would have to be extended far beyond the distance hitherto regarded as necessary. Finally, it may be said that the amount of organisation, supervision, labour, and expenditure devoted to the experiment has been greater than would be possible in any ordinary Indian town of similar size and population. The operations carried out at Mian Mir cannot, therefore, be taken as typical of what might ordinarily be done in Indian towns, and still less in Indian rural districts. In discussing the applicability of the methods adopted in Ismailia, Panama, and elsewhere the commissioners state that the facts which they have summarised on this part of the inquiry do not lead them to conclude that anti-malarial measures such as have been carried out in these places can be readily adopted in India with the assurance of speedy and certain success. The problem, the commissioners add, is one of immense complexity and difficulty, and unhappily no satisfactory solution is yet in sight. Nevertheless, it may be accepted that anti-larval measures combined with quinine prophylaxis offer great possibilities; the Government therefore should not be deterred because of the magnitude of the task or the uncertainty of the issue. In the opinion of the investigators the work for the immediate future lies in patient and searching inquiry and in careful and continued experiment. It is essential for the wide success of any measures that they should have the active coöperation of the people whose interests they are intended to serve, and that they should go hand in hand with general improvement of the sanitary environment of the Indian people whose education in this direction lies at the root of the problem.

Partial Enterocele in an Obturator Hernia.

IN THE LANCET of Oct. 15th there was recorded by Dr. H. LEWIS BARKER a case of Richter's hernia strangulated in the obturator canal. Richter's hernia, as it is most commonly called nowadays, or partial enterocele as it is better named, is a decidedly rare condition, and even since it was first described it has often been confused with other conditions somewhat similar. The essential point in a partial enterocele is the inclusion within the hernial sac of less than the whole circumference of the bowel. In fact, in the majority of cases, the portion included in the sac is less than half the circumference. It is somewhat difficult in accounts by the older writers to be certain what was the condition which they wished to describe, and so it is not easy to determine when this form of hernia was first recognised. In 1700 LITTRE of Montpellier described a form of hernia which had not previously received recognition, for in it the piece of bowel involved formed a pouch-like projection from one side of the bowel. It appears to be fairly certain that in two of the three cases which he had observed the strangulated portion was what we now know as a Meckel's diverticulum. It is possible that the third case was really a partial enterocele, and this is probably the reason why the name of LITTRE was given to this variety up to comparatively recent years. As Sir FREDERICK TREVES, however, has pointed out, LITTRE apparently confused two conditions, for, at all events, two of his cases were examples of strangulation of a diverticulum. The same observer showed that the true partial enterocele was first clearly described by RICHTER in 1778, and therefore suggested that it would be better to confine the name Littre's hernia to the hernia of a diverticulum and to give the name Richter's hernia to the partial enterocele.

We agree that if the names of persons are to be given to diseases or other morbid conditions it is desirable that the name of the author of the earliest description should be employed. But if this rule is to be followed in this case, partial enterocele should be called "Lavater's hernia," for his description was published in 1755, and it was probably written much earlier. While willing to give the credit to all these pioneers in the description of different forms of hernia we think that we have here an excellent illustration of the desirability of not using personal names in the titles which we give to morbid conditions; it is preferable to let the name be, so far as possible, descriptive of the disease. No real objection can be put forward against employing the term "partial enterocele" for that form of hernia which is now generally associated with the name of RICHTER, and hernia of the diverticulum for that which appears to have been described for the first time by LITTRE. When the greater part of the circumference of the bowel is involved in a partial enterocele, the signs and symptoms in no wise differ from those of an ordinary hernia, and if strangulation should occur the symptoms are well marked. If, on the other hand, less than half the circumference of the bowel is involved, the symptoms present, even if strangulation occur, may be remarkably slight. As no occlusion, or hardly any, occurs, there is no obstruction to the onward passage of the intestinal contents, no constipation is present, and vomiting may be infrequent and slight, and abdominal distension is generally absent. In this absence of severity of the symptoms lies the great danger from a partial enterocele, for perforation of the bowel may occur without the appearance of any symptoms suggestive of the likelihood of such an occurrence. It seems to be clear from the statistics that the form of hernia in which partial

enterocele occurs is chiefly the femoral, and therefore it is not surprising that the majority of cases occur in women.

In the case reported in THE LANCET recently the partial hernia was an obturator hernia, and this association is not so rare as would be thought, when we consider how rare any form of obturator hernia is; for the opening in the obturator foramen through which the bowel can make its way is very small, and it can only rarely happen that the whole circumference of the bowel is engaged in the sac. When this association does occur, when a partial enterocele takes place in the obturator opening, the danger of the situation is extreme, for in the first place the nipping of the gut may give rise to hardly any symptoms, and, in the second place, the depth of the hernia from the surface may cause no visible local prominence, and therefore the difficulty of recognising the condition early will be greatly increased. The treatment best adapted for a strangulated obturator hernia has hardly yet been determined. While some are still in favour of approaching the hernia by an incision below Poupart's ligament, most surgeons consider that the intraperitoneal operation gives a better view of the hernia and a better opportunity of dealing with the bowel if its vitality has been seriously lowered. There can be little doubt that the abdominal route offers many advantages.

The Bacteriology of Influenza.

DURING the epidemic which occurred in 1889–91 the disease known as influenza was investigated in a thoroughly scientific manner. We are not now concerned with the history of the malady, but it would seem probable that since about 1650 a disease with similar characters has now and again appeared in this country. Since 1891 there has scarcely been a single year but that a recurrence of "influenza" in one place or other has taken place. The clinical symptoms, however, have varied considerably, and numerous authorities are of the opinion that many of these outbreaks are of the character of "catarrhal fever" rather than of true influenza. This view is to some extent supported by bacteriological considerations, for although in the epidemic of 1889–91 PFEIFFER described a bacillus which has been widely accepted as the causal agent of the disease, this organism has not always been isolated during epidemics of more later years, but other microbes have been found, notably the micrococcus catarrhalis. Not only is this the case, but organisms indistinguishable from Pfeiffer's bacillus have been found in disorders which were not obviously of influenzal origin, so that there appears to be reason to believe that on the one hand what is clinically called influenza is not one disease but a series caused by different microbes, and that on the other hand the organisms hitherto described as bacillus influenzæ are not all identical with it, but belong to a group the various members of which possess very different pathogenic powers. The bacillus first described by PFEIFFER is very small, having about the same diameter as the bacillus of mouse septicæmia, but only half its length ($0 \cdot 2\mu$ by $0 \cdot 5\mu$). It is usually solitary, but it also occurs in chains of three or four. It is non-motile, and, so far as is known, does not form spores. It stains with some difficulty and is Gram-negative. It grows poorly upon artificial culture and is not easy to isolate, as the associated bacteria tend to outgrow it. It flourishes most readily upon culture media containing hæmoglobin or blood, but can also be cultivated upon glycerine agar-agar. This is the well-known and typical Pfeiffer's bacillus; the question is what relation it bears to other organisms resembling it, resembling it indeed so closely that the difference is imperceptible, which are found in conditions other than "influenza."

In the *Quarterly Journal of Medicine* for October is an article entitled "Influenzal Septicæmia, with a Short Review of the Present Status of Bacillus Influenzæ," by Dr. J. HUGH THURSFIELD, in which an interesting summary is given of this matter as it now stands. It is pointed out in this contribution that PFEIFFER and his followers laid down the proposition that where organisms of the bacillus influenzæ type are found there is a definite influenzal infection, and he called certain similar organisms which were found in non-influenzal affections pseudo-influenzal bacilli, attempting a differentiation on grounds of morphology only. Another observer, JOCHMANN, maintains that no essential morphological difference exists between the organisms derived from influenzal and non-influenzal sources. Although there is a general agreement among bacteriologists as to the morphological characters of the organism which PFEIFFER discovered, there is a wide divergence of opinion as to its occurrence in the blood, PFEIFFER and JOCHMANN declaring that when the organism appears in the blood it is usually a post-mortem or agonal phenomenon, while CANON and others claim to have found it in the blood in a large percentage of cases. In connexion with this subject the two cases recorded by Dr. THURSFIELD are of interest. From the clinical aspect, one patient was suffering from an attack of influenza, whilst in the second case there was no evidence of anything resembling such an attack, yet in each instance organisms were found in the blood which corresponded perfectly to the bacillus of Pfeiffer. The first case might justly be classed under the heading of influenzal septicæmia. We have already mentioned that Pfeiffer's bacillus, or rather one indistinguishable from it morphologically, has been found in other diseases. It is fairly frequent in the broncho-pneumonic patches of children dying from diphtheria, usually in conjunction with streptococci and pneumococci, and it has also been demonstrated in measles, in scarlet fever, and in the lungs of patients who have died from tuberculosis. Probably in these cases of mixed infection Pfeiffer's bacillus was only present as a saprophyte. A similar organism has also been found in whooping-cough, but here, as Dr. THURSFIELD points out, the question is more complicated. Some observers have not been able to distinguish the microbes found in this disease from Pfeiffer's bacillus, but BORDET demonstrated certain differences in cultivation which tend to show that the organisms described by him are not the same as those connected with influenza, but are the causal agent of whooping-cough. Further evidence was forthcoming in the appearance in the blood of specific immune substances. Another condition that has recently attracted attention is a purulent form of cerebro-spinal meningitis. In this instance also organisms have been found resembling both in morphological and cultural characteristics the

bacillus of influenza. COHEN, however, is of opinion that this form of meningitis is in reality a new disease due to an organism which, though in many respects similar to Pfeiffer's bacillus, can be distinguished from it by its pathogenic effects upon rabbits and guinea-pigs. Dr. THURSFIELD likewise mentions that similar organisms have been found in cases of otitis media, and in four cases at St. Bartholomew's Hospital in pus from the antrum of Highmore.

It will thus be seen that the presence of an organism conforming in every particular to Pfeiffer's bacillus does not necessarily indicate that there has been an influenzal infection. There would appear to be many "strains" of the bacillus, each possessing very different pathogenic powers, being in this particular somewhat similar to the characteristics exhibited by bacilli of the colon group. In some respects also a resemblance to the pneumococcus and other organisms is shown, in that although present in an apparently healthy body or in a lesion, they do not produce their usual morbid effects. Further, the bacillus of Pfeiffer has been found in the secretions of the nose and throat for long periods after an attack of influenza has subsided, and it has been suggested that in this manner the interval between one epidemic and another may be bridged over. The question whether such cases may come under the category of germ carriers offers an interesting field for further research. The points referred to by Dr. THURSFIELD are of importance and his remarks are well worthy of attention. Some of his conclusions can only be confirmed by further investigation should epidemics of typical influenza again break out, but other subjects to which he draws attention, such as the pathogenic organism of whooping-cough in the form of Bordet's bacillus, can be more readily inquired into. It would also be desirable that more positive information should be acquired in regard to the bacteriology of the frequent epidemics of so-called influenza, which are constantly occurring, but which have probably a different origin.

ON Wednesday last His Majesty the King conferred the honour of knighthood upon Dr. J. Kingston Fowler and Mr. A. Pearce Gould, investing them with the insignia of a Knight Commander of the Royal Victorian Order.

THE WORKMEN'S COMPENSATION ACT. — At Barnstaple (Devon) county court last week, before Judge Beresford and Mr. A. W. Lemarchand, sitting as medical assessor, the widow of a local slaughterman claimed compensation from a butcher for the loss of her husband, who died last May from anthrax. For the defence it was contended that the case did not come under the Act, as the deceased was not a workman under contract for service. He only worked two days a week for defendant and employed another man. The killing of the cattle took place at a slaughterhouse provided by the railway company and for which no charge was made, and the deceased provided his own tools. These facts, the counsel contended, were contrary to the ordinary relationship that existed between the master and servant. His honour was of opinion that the only question was whether deceased contracted anthrax during the time he was in the employ of the butcher, and as that was proved the widow was entitled to recover, and he awarded her £150

Annotations.

"Ne quid nimis."

THE DEATH OF PRINCE FRANCIS OF TECK.

THE death of H.S.H. Prince Francis of Teck removes from our midst one who as a man was deservedly popular among those privileged to be his friends, and who was indefatigable in the employment on behalf of others of the influence associated with his high position In the interest which he evinced in charitable work during the recent years of his life he followed worthily in the steps of many of his family, and with the practical good sense which is one of their leading characteristics, he knew how to concentrate his energies in one or two directions at a time so as to secure the fullest possible effect for the assistance which he proffered. Thus, having sympathy with manly training and with men in the making, he left a name that will long be remembered by many boys now growing into manhood in Hoxton; and thus also in espousing the cause of the sick and injured poor of London he associated his name and influence with the effort to relieve the needs of the Middlesex Hospital, and devoted time and personal effort to the substantial improvement of its financial position. For such work as that to which we have referred he was singularly fitted by personal gifts of disposition and manner, by a genial bearing towards his fellow men, and a simple courtesy free from all suspicion of effort or affectation. In that which he did on behalf of the Middlesex Hospital he had achieved marked success; the further endeavours upon which he was bent would have had the same fortunate issue, and we express our deep regret that on the threshold of middle age his career of usefulness should be cut short. Prince Francis had been suffering for some time from an affection of the nose. After his return from Marienbad, where it had been recognised as an empyema of the antrum, an operation was performed and the cavity was drained. On Sept. 28th the Prince went to Balmoral, and soon after arriving there he suffered from occasional paroxysms of cough with expectoration. He kept quiet and was not at any time exposed to chill. On Oct. 4th he was suddenly seized with severe pain in the right side; his temperature rose to 102·5° F., and a friction sound was detected at the right base. The signs of effusion gradually developed, and he was unable to travel south when the Court left on Monday, Oct. 10th. On the following day a consultation was held, and it was decided that he probably had an empyema, for which an operation would be necessary. The pneumococcus had previously been found in the expectoration. As there were then no urgent symptoms, and as his general condition had somewhat improved, it was decided, after a further consultation, that he should travel to London on Oct. 13th and proceed at once to the nursing home. He was seen on arrival, and at the examination the physical signs which had been reported were found. On the same afternoon, Oct. 14th, an exploratory puncture revealed the presence of a condition requiring early operation—this was performed the same evening. The fluid removed contained a pure culture of pneumococcus. After the removal of the pressure upon the lung by the opening and draining of the pleura, examination showed that an excavation existed in the right upper lobe and that the pneumococcal infection had spread from the lung to the pleura. The temperature fell to normal on the morning of Oct. 15th, but there were no other signs of improvement. The temperature rose again for three days, and then for four days it was normal. The toxic effects upon the nervous

system were very pronounced throughout the illness and in the early hours of Saturday, Oct. 22nd, the heart began to fail, the patient passing away at 11 A.M.

INCARCERATION FOR LIFE AND ITS CONSEQUENCES.

JUST 12 years ago the Italian anarchist Luccheni was sentenced to life-long imprisonment at Geneva for the murder of the Empress of Austria as she was entering a steamboat on that lake. It was said at the time that he selected his opportunity so as to commit the crime in a canton where the death penalty had been abolished. However that may be, he was sentenced to solitary confinement within the prison of Evechê, and for a time seemed to reconcile himself to his fate with a cynicism which might pass for equanimity. But in his case, as in well-nigh every other of the kind, symptoms of mental alienation betrayed themselves, mainly in explosions of anger accompanied with violence, in one of which he nearly killed the director of the prison, M. Perrin. Since then, the surveillance imposed on him having been made more stringent, the isolation, and the morbid brooding, intellectual and moral, which it encourages, began to tell, and he was closely watched as an inmate whose next outburst might be homicidal or suicidal, or both. Set to work at bookbinding, an occupation which seemed to soothe him, he had his work prescribed for him a few days ago by the head of that *métier*, but in a sudden access of discontent, passing into rage, his language and demeanour became so aggressive that he was consigned to his cell to await "discipline." No sooner had the door closed on him than his fury became maniacal. He seized every utensil within reach and hurled it through the window, endangering the wayfarers in the street below with the débris, and attracting a crowd to the spot. This brought the new director, M. Ferres, accompanied by six able-bodied keepers, to his cell, where, after a violent struggle, he was pinioned and placed in an underground place of detention. Such explosions, occurring so frequently in the case of criminals expiating the life-penalty in seclusion, are now regarded in Italy as the inevitable outcome of the treatment, and, issuing as they do in chronic mania and finally in dementia, are already reviving discussion as to the justice, or the wisdom, of exposing the felon to such a fate. A few months ago Passanante, who attempted King Humbert's life in 1878 when on a royal progress through Naples, died, prematurely, a decrepit imbecile in the asylum for the criminal insane at Montelupo in Tuscany, and the miserable spectacle he presented for years before sufficed to awake misgivings in Italian medico-legal circles as to whether the gallows or the guillotine might not appropriately resume its function, after more than a generation's experience of the futility of solitary imprisonment for life as a deterrent and of its cruelty as a penalty. Reference was made in the course of discussion to the classical debate on capital punishment in our House of Commons in the late "sixties" of last century, when John Stuart Mill powerfully advocated its retention on the ground of humanity, and another authority, Sir George Bowyer, clinched that thinker's argument by facts drawn from his experience of Italy as to its deterrent value. Since then M. Briand, the French Premier, has seen the wisdom of a return to the guillotine, after the non-success of its quasi-humanitarian substitute, "burial alive within four walls," in checking the rising, spreading "tide of bloodshed" among the civil population. A similar revulsion of feeling and conviction is apparent beyond the French frontier, and the suicide of Bresci at San Stefano, the tragic "life-in-death" of Passanante at Montelupo, and now the maniacal outbursts and terrible fate of Luccheni at Evechê, will go far to bring about the revival of a punitive method rescinded on grounds of sentiment rather than of legislative wisdom. Luccheni committed suicide in the subterranean cell to which he had been relegated a few hours before. His violence in demeanour and language had so far calmed down that his keepers allowed a brief interval to elapse before renewing their watch over him. He had indeed been singing gaily after being removed to the strong room, and it was with something more than surprise that at 6 P.M. on the occasion of the evening visit he was found dead, suspended by his leathern waist-belt from the iron grating of his window. Post-mortem examination is expected to yield results, particularly as to the cranium and its contents, which will give peculiar interest to the medico-psychological report on the man and his history. Megalomania, or the symptoms which lead up to it, were, in the opinion of more than one specialist, in evidence not only at the trial in November, 1898, but also during the years of subsequent detention, in so much that his repeated outbursts of rage, invariably coincident with "wounded *amour propre*," came to be looked for as inevitable on every occasion when the discipline or the work connected with it was not to his taste or liking. According to some who have been interested, psychologically, in his case, his intense love of notoriety, his eager craving to "get talked about"—conspicuous throughout his whole career in society or when excluded from it—explains the act of self-murder which makes his fellow prisoners congratulate themselves (according to the Italian journals) on having been thus relieved of an eminently disagreeable, not to say dangerous, companion.

THE PHYSIOLOGICAL STANDARDISATION OF CARDIAC DEPRESSANTS.

IN the *American Journal of Pharmacy* for October Dr. Thomas S. Githens and Mr. Charles E. Vanderkleed contribute an account of their work on the physiological standardisation of cardiac stimulants and depressants. Of the former class they worked on apocynum, convallaria, digitalis, squill, and strophanthus. So much has been published on the standardisation of these drugs that it need only be mentioned that the investigation throws light on the amounts required to produce certain effects, a phase of the subject which has received but little attention. The group of cardiac depressants includes aconite, gelsemium, and veratrum, and nearly related to them is another group, including physostigma, lobelia, and conium, which act chiefly on the voluntary muscles and kill by respiratory rather than cardiac failure. The investigation showed that with all these drugs toxic symptoms are manifested even under the influence of comparatively small doses, whereas with drugs of the digitalis series a dose slightly less than the toxic dose causes only slight toxic phenomena. On this account the dosage of the cardiac depressants is not as sharply defined as that of the cardiac stimulants, and in making a standard for these drugs it is necessary to fix an arbitrary period of time within which the animal should die, the period suggested being three hours. The heart depressants are characterised further by the production of evident effects when given in sub-lethal doses. Thus, aconite causes violent retching, gelsemium is likely to produce convulsions followed by paralysis, while veratrum stands between them in regard to these phenomena. The drugs which cause death by failure of the respiration—viz., conium, physostigma, and lobelia—can all be standardised by chemical means, as their activity is largely dependent upon their alkaloidal content. But in the case of aconite, gelsemium, and veratrum, although their activity depends upon the presence of certain alkaloids, their physiological activity is not necessarily proportional to their alkaloidal strength. The physiological activity of aconite is mainly

due to aconitine, but this alkaloid is liable to split off a methyl or a benzoyl group during the preparation of galenicals, whereby the aconitine becomes inactive although capable of responding to the chemical reactions of an alkaloid. This is particularly likely to occur when the preparations of aconite are kept for a long time. Veratrum contains an active alkaloid, veratrine, together with several inactive alkaloids, and similarly gelsemium contains gelsemine and gelseminine, of which the former has practically no effect upon mammals. In the case of these drugs, therefore, it is necessary to standardise by physiological means, in order to avoid the misleading results that may follow from a chemical assay. The method adopted consists in determining the amount of the preparations of these drugs that proves fatal to guinea-pig within three hours. It was noticed in the case of gelsemium that the tincture was much more toxic than the fluid extract, on the basis of equivalent amounts of total alkaloid, while in the case of aconite just the opposite result was obtained. It seems probable that the prolonged percolation which occurs in the preparation of the tincture dissolves a higher proportion of the intensely active gelseminine. In spite of the diverse chemical characters of the alkaloids of veratrum, it was found that the activity of its preparations agreed quite closely with the percentage of alkaloids present. It is the intention of these investigators to continue the comparison of the results of physiological and chemical methods of assaying drugs, including a series of comparisons with conium, physostigma, and lobelia.

SANITARY CONDITIONS AND INFANT MORTALITY IN LANCASHIRE TOWNS.

THE Registrar-General's list of large towns dealt with in his weekly returns includes 15 towns in the county of Lancaster, with an aggregate population estimated to the middle of this year at very nearly 3,000,000. The mean reported annual rate of mortality in these Lancashire towns during the past summer quarter was equal to 14·5 per 1000. It may be well to compare this death-rate with the rate of mortality in the county of London during the same period, which did not exceed 11·0 per 1000. Thus the rate of mortality from all causes in the Lancashire towns exceeded that which prevailed in the whole county of London, with a distinctly urban population little short of 5,000,000, by more than 30 per cent. One of the main causes of the excess of mortality last quarter in the Lancashire towns was the greater fatality of diarrhœa, principally infantile, which caused an annual rate of 1·48 per 1000, nearly three times as high as the rate from the same cause in London, which was but 0·55 per 1000. Fatal infantile diarrhœa is now recognised as to a large extent the result of neglect and ignorance in the treatment of infants. It seems improbable that the proportion of the population suffering from actual poverty is smaller in London than in the aggregate of the Lancashire towns, and therefore it is difficult to explain this marked excess of the death-rate in the Lancashire towns otherwise than as the result of less efficient sanitary administration than obtains in London. It is indeed impossible to doubt that the excess of mortality in the Lancashire towns, compared with London, implies a lower standard of sanitary condition, and such a conclusion is supported by comparison of the statistics of infant mortality during the past summer in the Lancashire towns and in London, the results of which comparison are not affected by the probable over-estimate of the present population of many of our largest towns. During last quarter the deaths of infants under one year of age in London did not exceed 95 per 1000 of the registered births, against 129 and 109 in the corresponding periods of 1908 and 1909. In the 15 Lancashire towns, however, the mean rate of infant mortality last quarter was equal to 143 per 1000 births, showing an excess of more than 50 per cent. upon the London rate; in the summer quarters of 1908 and 1909 the mean rate of infant mortality in these 15 towns was 171 and 134 per 1000 respectively. In these Lancashire towns the rate of infant mortality last quarter ranged from 96 in Barrow-in-Furness, 98 in Rochdale, 103 in Warrington, and 113 in Oldham, to 157 in Bury, 158 in Wigan, 161 in Bootle, 179 in Burnley, and 209 in Preston; thus in each of the 15 Lancashire towns was the rate of infant mortality last quarter higher than in London. It is specially noteworthy that whereas, speaking generally, the rate of infant mortality last quarter in our largest towns showed a distinct decline from the rate recorded in the same period of last year, the rate was actually higher in 11 of the 15 Lancashire towns, and only showed a decline in Liverpool, Wigan, Bolton, and Bury. These facts call for the serious attention of the urban sanitary authorities in Lancashire, and of the ratepayers by whom those authorities are appointed. The much-needed decrease in the loss of life and health of infants in our urban populations will not become general until a rate of infant mortality exceeding 100 per 1000 births is fully recognised as discreditable to the community in which it continues to prevail.

VISUAL DISTURBANCES OF PSYCHICAL ORIGIN.

APART from the familiar diplopia and polyopia of hysteria there is a little known though well-defined disturbance of vision of central origin to which the term "dysmegalopsia" has been applied. The word signifies defective visual recognition of the real size of objects, which are usually thought to be either larger or smaller than their normal dimensions—macropsia and micropsia are the terms used to denote these changes. Micropsia may occur from paralysis of accommodation, but ordinarily it is due to some lesion in the visual centres, and similarly with macropsia. In fact, two types of dysmegalopsia have been distinguished by Fischer: cortical dysmegalopsia, a condition that follows anatomo-physiological laws, and transcortical dysmegalopsia, which follows psychical laws. The nature of the cortical lesion has not been determined, and indeed the literature on the subject is very meagre; yet the cases that have been described, by reason of the definiteness of the symptomatology, are of the greatest interest. A new instance of the condition, furnishing apparently unique features, is recorded by Dr. Liebscher of the Irrenanstalt in Brünn in the *Monatsschrift für Psychiatrie und Neurologie* for August. His patient was an arterio-sclerotic of 62 with typical involution melancholia, including auditory hallucinations. He complained that everything he looked at was shaking or vibrating, especially if his left eye only was used. Frequently micropsia was observed. Objects appeared to the patient smaller than they really were. Frequently, too, the upper parts of letters of the alphabet placed vertically seemed to him to be "broken" and to be bent to the left. A remarkable feature of the visual defects was that sometimes the left side of any object appeared larger than the right; thus the examiner's face seemed to be swollen on the left side; a square seemed to be an irregular four-angled figure; a circle was drawn out into an ellipse on the left. The patient was unable to indicate correctly the length of objects under certain conditions; when two matches were placed parallel to each other he imagined that one was longer. A curious fact was that the process of vision was associated with a most unpleasant feeling; people he looked at seemed "to be sticking in his eyes," especially if they came near. Repeated ophthalmological examination failed to discover any defect whatever in media, eye movements, optic discs, or retinæ. There was not the

slightest trace of nystagmus, and the patient's eyes were fixed easily and instantaneously on any object presented to him, yet it appeared to him to be shaking or vibrating. The explanation of this interesting phenomenon is thus given by the writer. It is well known that in nystagmus the patient commonly declares the object to be still, although his eyes are moving; in the present case the object seems to be moving although the eyes are still—in a sense the converse of nystagmus. In the case of nystagmus the patient has learned to combine the visual impressions obtained from the stimulation of different parts of the retina into one, whereas it is clear that in the writer's case only one part of the retina is being stimulated, yet the patient gets the impression of a moving picture. The presumption is that hypersensitiveness of the retina leads to its becoming momentarily functionless as the result of what is for that retina too strong a light stimulus; it recovers immediately, but again becomes fatigued by the continuance of the stimulus; thus, as long as the patient gazes fixedly at an object it appears to be "coming and going"—in other words, to be vibrating. In this connexion the phenomenon of star-twinkling occurs to the mind. The hyperæsthesia of the retina is linked to the unpleasant affective tone accompanying the process of vision; the patient complained bitterly if people came too near him. The explanation of the other disturbances is not simple, and would take us too far into the question of spatial projection and false localisation in space.

DOES A BLACK SKIN PROTECT AGAINST MALARIA?

IN a recent issue of a daily paper we find it stated on the anonymous authority of a "well-known London doctor" that blackness of the skin, however produced, protects against malaria, and it is said that "if you are going to a country where malaria is rife stain yourself all over with walnut juice, or black yourself with burnt cork, and you will be less liable to catch the disease." And the explanation is given that the browning of the skin prevents the actinic rays of sunlight penetrating the skin, and so helping the malarial parasite to mature; and therefore we are told "if white men had artificially coloured skins, or even wore black underclothing, they would be in the same position as the natives—protected to a certain extent against the malarial parasite maturing." We should be interested to know on what facts the "well-known London doctor" bases his statement. It is true that, on the whole, the coloured races suffer less severely from malaria than the white races, but we are not aware of any evidence which even suggests that this is due to the colour of the skin. Of course, it is possible that the staining of the skin with walnut juice or burnt cork may have a deterrent effect on the mosquito and so prevent the inoculation of the parasite, but this, we should imagine, was more than doubtful. The immunity of the savage races is probably the result of evolution by selection.

ACUTE PANCREATITIS.

ACUTE pancreatitis is still an obscure disease, and it is generally impossible to diagnose its existence from other acute abdominal conditions until the abdomen has been opened, and even when this has been done the diagnosis is often far from easy. The etiology of the condition is still puzzling. Medical treatment is very unsatisfactory, and though many operations have been performed very few recoveries have been recorded. As to the results of surgical treatment it is hardly safe to base an opinion merely on the recorded cases, for successes are much more likely to find their way into print than are failures. In 1908 Mr. Mayo Robson was able to collect 59 cases in which an operation had been performed, and of these 23 recovered, but these statistics certainly do not represent the true proportion of successes. In the present issue of THE LANCET is recorded a case of acute pancreatitis under the care of Mr. A. E. Barker, in which two operations were followed by recovery. The diagnosis was made during the operation and it was based chiefly on the discovery of patches of fat necrosis in the great omentum. At the second operation extensive fat necrosis was found also in the retroperitoneal tissue, and a large collection of inflammatory fluid was evacuated from the lesser sac. Complete recovery followed, and we congratulate Mr. Barker on the issue of his very interesting and successful case.

THE DIAGNOSIS OF TWIN PREGNANCY: A NEW SIGN.

THE recognition of a multiple pregnancy is often a matter of some difficulty, and although the more frequent practice of abdominal palpation renders the possibility of its being overlooked less likely, yet even at the present day, according to most authorities, it is not recognised before the birth of the first child in more than 50 per cent. of the cases. Capuron, after having been a teacher of obstetrics for 50 years, one day said to Pajot, "There is but one way by which you may know a twin pregnancy; if you have seen one fœtus born and find that there is another in the uterus you may be sure there are twins." We are not nowadays quite so unable to prophesy, but in some cases the certain recognition of the presence of more than one child in utero may be almost impossible. Quite recently, indeed, at a large London lying-in hospital a case was operated upon by Cæsarean section for contraction of the pelvis, and only when the uterus was opened was the presence of a second child discovered. Such mistakes should be rarer and rarer as the practice of abdominal palpation becomes more prevalent and greater skill is acquired in this method of examination. There is no lack of signs which may indicate the presence of a twin fœtation; it is their certain recognition which is so often difficult. The finding of two bags of membranes, the existence of a furrow between the two fœtuses, the presence of too many small or large fœtal parts, the large size of the abdomen, the apparently excessive length of the fœtal axis, and the auscultation of two hearts beating at different rates, while all valuable diagnostic aids, may not be present or their significance may be misunderstood. The diagnosis of a twin pregnancy before labour sets in is a matter of no little importance to the mother and cannot fail to bring credit to the medical attendant. In spite of this, in a very large percentage of the cases the condition is overlooked, and any addition to our knowledge therefore which will prevent such mistakes in future is to be welcomed. Dr. C. J. Gauss believes that he has discovered a sign of considerable importance in this connexion, and in a paper recently published in the *Zentralblatt für Gynäkologie*[1] lays stress upon the presence of an anterior parietal presentation in the case of the first of twins when it is presenting by the head, as a point of considerable diagnostic value. As a result of the small size of the head and of the leverage action produced by the second child upon the body of the first, due to the want of space in utero, he maintains that this presentation is to be met with in so large a proportion of twin pregnancies as to render it of great value. In several cases where the diagnosis had proved impossible by the abdomen the presence of such a presentation has led him to the successful recognition of a twin pregnancy. An anterior parietal presentation, corresponding as it does to a marked degree of Naegele's obliquity

[1] Zentralblatt für Gynäkologie, No. 40, 1910, p. 1281.

and associated with abnormally easy recognition of the anterior ear, occurs so infrequently in a normal pelvis as to render its occurrence in such conditions most suggestive of a twin pregnancy. This sign has the drawback that it is not available until labour has commenced, and it is, of course, only present when the first child presents by the head, but such a presentation occurs in some 70 to 80 per cent. of all twin pregnancies. It should therefore, if further observations tend to show that it is as constant an occurrence as Dr. Gauss supposes, prove of considerable value in helping to make a diagnosis in doubtful cases of multiple pregnancy. The question is well worth further investigation, and in our opinion this physical sign has only one drawback—namely, it involves for its recognition the necessity for making a vaginal examination, whereas most of the other signs of multiple pregnancy can be recognised when present before the onset of labour and by examination of the abdomen only.

GARDEN CITIES AND TOWN PLANNING ASSOCIATION.

IN giving prominence to the appeal of this association for funds in order to establish its work upon a firm financial footing, we wish again to express our approval of the objects which it seeks to accomplish and the means adopted. The operation of the new Housing and Town Planning Act calls for serious and zealous attention, and this association is largely responsible for the great practical interest now being taken in garden city and garden suburb schemes. But useful and praiseworthy as are the efforts to create garden suburbs and garden villages, it would be a grievous mistake to treat them all alike as entirely satisfactory compensations for the detrimental conditions as to health and physique under which the dwellers in large manufacturing towns suffer who are divorced from nature. There are garden suburbs and garden suburbs. The development of the true garden city scheme depends upon the decentralisation of industry; this scheme affords the artizan the opportunity of combining the advantages of town and country life, and as the welfare of our race in the future depends upon a satisfactory solution of the difficulty of securing healthy and happy conditions of life for the industrial worker and his family, it is sincerely to be hoped that the Garden Cities and Town Planning Association, 32, Birkbeck Bank Chambers, W.C., the only society which advocates and organises the control of a separate town or city with a fixed relation to surrounding agricultural land, will receive that measure of support which its treasurer, Mr. Francis E. Fremantle, claims from all those who feel the importance of the subject in its physical and moral aspects.

SPEECH IN CASES OF CUT-THROAT.

IN THE LANCET of May 22nd, 1909, p. 1501, a letter appeared detailing a case of cut-throat in which the question arose whether it was possible for a person whose larynx had been divided above the vocal cords to speak so as to be understood. We then, in commenting on this case, expressed the opinion that the speech of such a patient might be quite comprehensible. In the *China Medical Journal* of May this year Dr. E. M. Merrins of Wuchang has reported a case in which a man attempted to kill himself by cutting his throat. The knife passed completely through the larynx just above the true vocal cords. An attempt was made the next day to suture the severed thyroid cartilage, but the patient tore the wound open and no further operative treatment was adopted. Dr. Merrins tried to see what power of speech the man possessed. The attempt was made about a fortnight after the injury, but the wound still gaped wide above the vocal cords. With the wound exposed he was able to speak so as to be easily understood, but it was a weak whisper. When the throat was bandaged he was able to speak much more distinctly, and when the neck was flexed so as to close the wound he was able to speak clearly and well. The question of the possibility of comprehensible speech after a severe cut-throat wound may easily be of great medico-legal importance, and we believe that all surgeons who have had much experience of cut-throats will agree with the opinion we expressed last year, that comprehensible speech is perfectly possible, even though the larynx is divided immediately above the vocal cords.

DEATH AFTER THE REMOVAL OF TONSILS AND ADENOID GROWTHS.

IN the *American Journal of the Medical Sciences* for September Professor Francis R. Packard has reported a remarkable case of death following the removal of the tonsils and of adenoid growths. He finds that a mistaken impression prevails among general practitioners that the operation is comparatively safe. He regards the operation as so serious that he thinks it ought to be performed in hospital instead of at the patient's home. Ether he believes to be the safest anæsthetic, and he has never known a case of death which could be attributed to it, though he has personal knowledge of three cases in which death occurred after the administration of chloroform, in which nothing else had been done which could have been fatal. Except in cases where he is certain that his directions will be rigidly carried out regarding preparation for operation, he requires his patients to enter hospital the day before operation, and after operation he keeps them there for at least 24 hours longer if there is any elevation of temperature or other important symptom. The following is the fatal case which Dr. Packard uses as the test for his remarks. A girl, aged three years, was brought to him with the history that she had been perfectly healthy until a year ago. During the past two months she had suffered from frequent coughs and colds, and constantly slept with her mouth open. She had become languid and had little appetite. On examination she was apparently healthy except for a somewhat sallow complexion. This her mother attributed to frequent bilious attacks. The tonsils were rather large, with wide-open crypts, some of which contained cheesy material. Digital examination showed a large soft mass of adenoid tissue blocking the naso-pharynx. The heart and lungs were normal. At 1 P.M. on Sept. 30th, 1909, she was anæsthetised for operation. The anæsthetisation was started with ethyl chloride and followed by ether given by the drop method until she was unconscious. Then the ether was administered by a vapourising apparatus through a metal mouth-piece. There was much mucus in the nose and throat during the operation. The total amount of ether used was three ounces. The tonsils were loosened on both sides by blunt dissection. The left was removed by digital manipulation and dissection with scissors. The right was removed with a small guillotine after freeing it from the surrounding tissues. The adenoids were then removed with a forceps. Considerable bleeding followed, but at the conclusion of the operation there was no active bleeding. The anæsthetisation lasted 14 minutes and the child was on the table 10 minutes. About 30 minutes after the operation, when she was recovering from the anæsthesia, her pulse was good. At 4.30 P.M. her throat was examined and no bleeding could be seen. At 5.30 the nurse noticed that her colour was not good, but there was no evidence of bleeding. The pulse was good and she seemed in fair condition. At 6.30 the temperature had risen to 100° F., the respirations to 36, and the pulse to 156. A tongue depressor was inserted to see if there was any bleeding, and this caused her to vomit. Something appeared to occlude her larynx, and tracheotomy was performed, but no cause of obstruction could be found, and the child died

about 7 P.M. A necropsy was not allowed. Professor Packard regards it as practically certain that death was due to the status lymphaticus.

THE MYSTERIOUS DISEASE IN SUFFOLK.

A COMMUNIQUÉ has been received by the press from the Local Government Board dealing with four deaths which occurred over a month ago at Freston in Suffolk. As a result, the fact has now become public that there were grounds for believing these deaths to have been due to plague, the pneumonic symptoms, which were puzzling, being capable of explanation in this way. We were glad to observe that the occurrence of these deaths caused little comment at the time, as undoubtedly considerable public apprehension, and much of it of a needless kind, would have been aroused by the belief that plague had established a foothold in this country. Nothing of the sort has happened. A bacteriological examination was made in regard to material taken from two of the patients, and although opinions were not unanimous, it certainly seemed possible that the pneumonia had been due to plague. Subsequently rats and hares found dead or dying in the same locality have been examined on behalf of the Local Government Board, and of these three rats and one hare have been found to be infected with plague. In consequence the rural district council has held conferences with Dr. H. T. Bulstrode, of the Local Government Board, and every sort of systematic effort to destroy rats and remove accumulations of refuse is being undertaken in the most thorough manner. Having regard to this activity on the part of the authorities, and to the fact that no cases of human illness suspicious of plague have occurred since Sept. 26th, we feel justified in saying that there need be no serious anxiety about the outbreak.

THE CONSERVATIVE SURGERY OF THE EXTREMITIES.

IN the last Archives of the Middlesex Hospital Sir Henry Morris has emphasised the value of conservative treatment in injury and disease of the extremities. In cases of severe injury to the hand he has refused to amputate when sent for to do so, and practised conservative surgery with gratifying results. His rule is not to amputate through the forearm for an injury of the hand because of extensive laceration of the skin, crushing of the fingers, and fractures of the phalanges if the main vessels and nerves at the wrist are not damaged. He simply trims away skin or parts of digits that are hopelessly beyond recovery, and for the rest cleans the part thoroughly and wraps the whole hand in lint soaked in carbolised oil. Afterwards, instead of removing the lint he daily re-saturates it by pouring on fresh carbolised oil. In this way he has allowed the same lint to remain covering the injured part for 8, 10, or 14 days or longer. When the lint is taken off it will be evident what tissues will recover and what will have to be removed, either by nature alone or assisted by surgery. To save even only one digit will generally provide a more useful extremity than a hook or any form of artificial hand short of the most elaborate and costly. Occasionally there may be disappointment, and the removal of a cumbrous bone or a stiff and useless finger may be necessary. But, as a rule, the surgeon will be gratified by the patient returning after some time, perhaps years, to express his gratitude and show with pride the use he can make of his partial and unshapely hand. It is, of course, important to save any part, even the merest stump, of the thumb. If the muscles which oppose the thumb to the digits be not entirely damaged, and especially if any part of any one of the fingers has been spared and its flexor and extensor tendons still have some action, it is wonderful to what varied and great use this remnant of a hand can be put. Sir Henry Morris was one day accosted by a railway porter who showed him with great thankfulness a hand consisting of a broad, strong palm and a stunted thumb and little finger. Many years before he had been sent for to amputate the forearm, but had only trimmed off some skin and fingers. The man had been able to do all his work satisfactorily. In operations on the extremities for disease, such as caries, necrosis, and tumours, Sir Henry Morris also recommends conservatism. A young woman came under his care in 1876 with myeloid or endosteal sarcoma of the lower end of the radius. Instead of amputating he excised the lower ends of the radius and ulna, and left the patient with a very useful hand. There was never any recurrence, and she brought up a large family and used her hand well for housework. Loss of more or less of the foot is not so important as a corresponding loss of the hand, but Sir Henry Morris advises here conservatism also in injury and disease of the lower extremities. Though the movements of the hallux are much more restricted than those of the thumb, the advantages of a foot as entire as possible, both for security in standing and for spring and elasticity in walking, are considerable.

AT the Surgical Section of the Royal Society of Medicine on Nov. 8th a debate will be held on "The Treatment of Fractures in the Neighbourhood of the Joints." The discussion will be opened at 15, Cavendish-square, W., at 5.30 P.M., by Mr. Robert Jones (Liverpool). Fellows and members of the section who wish to take part in the debate are requested to send their names to the senior honorary secretary of the section, Mr. Jonathan Hutchinson, 1, Park-crescent, London, W.

THE TREATMENT OF SYPHILIS WITH EHRLICH'S DIOXYDIAMIDOARSENOBENZOL.

BY SANITÄTSRAT DR. WILHELM WECHSELMANN,

PHYSICIAN IN CHARGE OF THE DERMATOLOGICAL DEPARTMENT OF THE RUDOLF VIRCHOW HOSPITAL IN BERLIN.

(*Translated for* THE LANCET.)

Professor Paul Ehrlich has for several years been engaged in systematic attempts to discover chemical substances which might be serviceable in the treatment of certain infectious diseases—namely, those in which the natural recuperative powers of the system, assisted by the formation of specific antibodies, are unable to bring about a restoration of health. The new system of treatment has been called chemotherapy, and in the preliminary investigations hundreds of chemical compounds were prepared and tested on infected animals without satisfactory results being obtained. All of these earlier preparations acted destructively on the antibodies; while attacking the protoplasm of the parasites they caused organic lesions in the animals. It therefore became necessary to discover substances capable of destroying the parasites, or, which comes to the same thing therapeutically, capable of hindering their propagation—a mode of action which Ehrlich has called sterilisatio magna—and at the same time not injurious to the patient, at least in the doses required for the destruction of the parasites. Among hundreds of such preparations it was found that dioxydiamidoarsenobenzol in its action on spirillosis in animals was the one which best fulfilled these conditions.

Dr. Hata, to whom Professor Ehrlich entrusted these experiments, found that after the remedy was taken into the system the spirilla of fowl spirillosis and of relapsing fever disappeared immediately; in observations on rabbits it was seen that primary ulcers swarming with spirochætæ healed rapidly, and in 24 hours the animals were free from spirochætæ. With the object of bringing the remedy into use for the treatment of patients

Alt made many trials of it on paralytics. These observations showed that the substance, which was in every instance tolerated by monkeys in doses up to 0·15 gramme per kilogramme of the animal's weight, had no poisonous action on the human subject in doses varying from 0·3 to 0·5 gramme. Iversen then reported gratifying results in relapsing fever, and Schreiber observed that the symptoms of syphilis very soon disappeared under treatment with this preparation. In March of the present year Professor Ehrlich sent me a sample of it for further trial. I soon recognised that in some instances recovery was possible in the case of suckling infants infected with syphilis and so invaded with spirochætæ that a fatal issue seemed inevitable; necropsy of those which perished revealed no evidence of arsenical action on the internal organs. Several observers, such as Truffi, Pazini, and especially my assistant Dr. Siesskind, have proved that the spirochætæ disappear from papules and primary affections, in some cases after 24 hours, while in other cases they still exist after days. Iversen has lately made similar observations in preparations of glands.

At the present time there is a great distrust of new arsenical preparations. It was therefore necessary to prove that the new remedy was far superior to others of a like kind, and I began by trying it on incurable cases. In the year 1906 a male patient, aged 18 years, came under my care on account of a malignant form of syphilis which did not yield to injections of calomel and Zittmann's treatment. He was next attended by Professor Buschke, and in October, 1906, he had a syphilide of a cockade pattern on the body, ulcerative invasion of the fauces, thickenings of the bones, and more particularly on the glans and on the penis eight deep ulcers as large as peas. Inunction, sajodin, injections of calomel, arsenic, steam baths, sulphur baths, and iodide of potassium were employed, but with so little success that in February, 1907, the patient's temperature continued for more than a week at 39° C. and the invasion of the fauces progressed. Inunction was resumed in March. On April 28th the eruptions had healed up in some places, partly by granulation, but those on the head were unchanged; the uvula had disappeared. Zittmann's treatment and iodipin were employed from April 28th to May 7th. Injections of corrosive sublimate were given on May 23rd and atoxyl subsequently, the latter being limited to three injections of 0·2 gramme; two courses of inunction were at the same time resolved on. Having refused further treatment the patient was discharged on July 6th. The ulcers of the fauces had in great part healed up with the formation of immense cicatrices, and some of the syphilide was also healed, but a patch about the size of a German mark (a coin similar to an English shilling) remained on the gluteal region. He very soon had to seek admission to the Charité Hospital, where he was treated with ten injections of atoxyl and six injections of calomel. In November he entered the Lichtenberg Sanatorium, where he had 32 inunctions, iodide of potassium, and sajodin. In April, 1908, destructive ulceration of the penis made its appearance. On May 20th he returned to the Virchow Hospital under Professor Buschke, and was treated with injections of arsenic, injections of calomel, iodised casein, iodide of potassium, and inunction. On August 31st he was discharged at his own request. In November and December of the same year he was treated in the Charité with calomel. From February to June, 1909, he had treatment with inunction in Lichtenberg. In August, 1909, he was again in the Virchow Hospital under Professor Buschke. From October to December he was treated in Lichtenberg with inunction and calomel. From January to March, 1910, he had the Josef treatment with inunction and iodide of potassium. It is therefore certain that every possible form of treatment had been employed without benefit.

On April 2nd, 1910, the patient was admitted into my wards. The miserable man then had on the inner side of the upper part of the thigh a bluish-red patch, partly cicatricial and partly ulcerating, about the size of the palm of a small hand; he had also on the crown of his head a similar patch measuring 2 centimetres by 6 centimetres diagonally with slimy serpiginous ulcers; several bones showed thickening, and there was ulceration in the throat. On the penis there was open slimy ulceration of the skin, the glans, and the ventral surface of the penis down to the fascia. He said that since the commencement of the disease in 1906 the penis had been superficially sound for only a few days. On April 13th he was given 0·25 gramme of Ehrlich's new remedy No. 606, whereupon rapid recovery began. After about four weeks the skin of the penis was lost once more (*zerfiel noch einmal*) and at the same time there was a thickening at the lower end of the right radius. On a second injection of 0·45 gramme being given on June 27th this healed in two days and the penis was almost completely covered with new skin after a third injection on August 8th. The patient was now quite recovered and fit for work.

A very similar history is recorded in the following case of incurable lues:

CASE 2.—A working girl, 25 years of age, was, in July, 1905, affected with lues and had received several inunctions and injections in the Charité. For years she had not been able to hold her fæces. On May 5th, 1909, she was received in my wards of the Virchow Hospital in very poor condition. She had a number of foul ulcers, each about two-thirds of an inch deep and 5 inches long, arcuate in form, mounting from the posterior commissure high upon the nates. There could be seen a few evidences of healing in the form of atrophic scars on the margin of which the progressing ulcers were located. The rectum was very much infiltrated, and showed two strictures which hardly admitted a finger, and upon which deep ulcerations were visible. Wassermann reaction, + + +; weight, 45 kilogrammes. She received five calomel injections, but they had to be given up on account of diarrhœa. Potassium iodide was continually given. From May 12th she received inunctions; the incontinence was somewhat improved; weight, 40 kilogrammes. The ulcers received treatment with the Roentgen rays. The patient left the hospital on July 3rd, although her condition was hardly improved, but returned after four days' absence. She then received calomel injections and local treatment with calomel, as she could not very well stand metallic mercury. On May 4th the patient received 0·3 gramme of Ehrlich's 606. After a few days a cleaning up and healing of the large abscesses commenced, and on May 18th the ulcers were entirely healed, with the exception of a few very small places on the right side. At the same time the condition of the rectum improved, and the rectoscopic examination showed only a simple erosion on the stricture. The general condition was very much improved; the weight remained at 40 kilogrammes. After a second injection the small erosions of the right side were almost entirely healed.

CASE 3.—A man, 23 years of age, showed seven months ago the first effects of syphilis; four weeks later there appeared an exanthem. From Nov. 28th, 1909, until the middle of March, 1910, he received 35 injections of mercury salicylate and calomel. For the past three months he had suffered from pains in both knee-joints. On May 5th, 1910, the patient was received into my wards in a very poor condition. He was very much emaciated, and his skin had the appearance of that of a corpse. The face looked like a Death's head with an expression depicting the highest pain. The whole body and face were covered with ulcerations, incrusted, which reached through the skin into the subcutaneous tissue, together with scars. There was a fœtid smell from the nose. The septum was perforated; the left concha and vomer were ready to drop off. There were large ulcerations in the naso-pharyngeal region, and the uvula was destroyed in its left side. The patient could hardly swallow, on account of the extreme pain, and had to be fed by injections through a tube. The pulse was very small and of poor quality, 120 and over. We did not dare to give an injection, but as his condition grew steadily worse under iodipin injections and as the end was to be expected in the very near future, 0·4 gramme of Ehrlich's 606 was injected on May 21st. The temperature did not rise and the pains did not amount to much. After two days there appeared a great improvement in his general condition, and on May 26th the beginning of a cure was everywhere apparent. On May 30th the uvula had healed. The ulcers were entirely healed. The bony support of the nose had been thrown off *in toto*; the fœtor had disappeared. On June 7th the patient could swallow and could walk around. His weight was, on May 21st, 41·5 kilogrammes; on June 5th, 42·5; and now 57 kilogrammes. He was discharged as cured.

From this time onward all the syphilitic patients were treated with the new remedy, and the symptoms almost always disappeared very quickly. Up to the present time I have treated over 1100 patients. Eroded chancres become clean after from 12 to 24 hours; in cases of marked sclerosis the cleansing process takes place with equal rapidity, but absorption requires longer. There were only four instances in which an exanthem appeared after the healing of the primary sore; in two of these patients it was seen to have disappeared spontaneously on the first and seventh day respectively after the injection, and the two other patients received a second injection. The plaques muqueuses of the mouth heal up in from 24 to 48 hours even if the patient smokes continually. Roseola fades in a few days, and the same occurs with malignant ulcerative syphilides, rupia, moist papules, the small papular syphilides which are under other conditions so refractory, and gummata. The large papular syphilides disappear more slowly, and with them a second injection is often necessary. The results are very favourable in syphilitic disease of the bones, nocturnal pains in the bones disappearing as if by magic.

This sudden stopping of the pains at certain hours can be explained only as the result of a killing of the spirochætæ, as the peculiar appearance of the pains in the bones during the night's rest can be explained only as a biological demonstration of the parasites. In view of experience with other

arsenical preparations, we could not but fear for the optic nerve. We therefore see that every patient has his eyes examined by a specialist before we give the injection. In cases in which there are changes in the optic nerve—a circumstance which quite often occurs—we have not given an injection save as explained below. According to animal experiments, a toxic influence upon the optic sphere is not very probable. It has been demonstrated that some aromatic arsenical derivatives produce in mice peculiar disturbances of coördination, these mice become dancing mice. Rötig has proved that these dancing mice show degenerations of the vestibular nerve, and some of them degenerations of the optic tract. These changes do not appear with the new remedy. And clinical observation seems also to favour the opinion that "606" can be used even in cases of diseased optic nerves. One of our first patients had not been examined for her eyes. After the injection it was found that she had received in my wards an inunction treatment, at which time the optic nerve on each side had had a dim margin and was venously hyperæmic (neuritis optica). The patient remained without any pathological affection of the fundus oculi and retained her full vision (Dr. Fehr).

Lately we have also seen that patients who have been treated with atoxyl or arsacetin stood "606" very well; in these cases also there was not observed any affection of the ocular organ, and this refers to several thousand cases. Even when there was a suspicion of the optic nerve being affected, and in patients suffering from atrophy of it, I have ventured to give an injection on the urgent request of the patient, whom I had made aware of the possibility of danger; this I did in the hope of checking the pathogenic process, and there has not up to the present time been any ill effect. It is even probable that recent optic neuritis may have to be treated with the new remedy as being of syphilitic origin; this is much more frequent than is generally supposed, and in our systematic examinations of patients suffering from secondary syphilis we have found it in about 3 per cent. of the cases. Incomplete recovery from this condition will probably be a factor in subsequent degeneration.

On other diseases of the eye, such as iritis and choroiditis, the remedy has an effect; in parenchymatous keratitis it may occasionally lead to some improvement, but is often of no use—probably because the slight vascularity of the tissue hinders the penetration of it by the remedy. Visceral syphilis, gummata of the testicle, syphilitic tumours of the larynx, icterus, epileptiform attacks of syphilitic origin, cerebral syphilis, paresis of the trochlearis and abducens muscles, and pulmonary syphilis were very favourably influenced. In tabes the subjective improvement was very great; there was almost always a diminution of the shooting pains which are often extremely severe, the unsteadiness of the gait became less, and incontinence of urine due to weakness of the bladder decreased. Whether the remedy produced these results by suggestion or by virtue of its salutary properties is not yet determined. Among the objective improvements a return of mobility in rigid pupils could be absolutely demonstrated in recent cases, but where degenerative processes were present this did not occur. The remedy may always be tried in tabes, because in this disease syphilitic changes amenable to treatment may co-exist with the sclerotic processes, and for the same reason a trial of it may be made in recent cases of progressive paralysis; in advanced cases I have not as yet seen any good result. Very advanced degeneration of the central nervous system and serious disorders of the heart and vascular system are to be regarded as contra-indications. According to our observations, made in conjunction with Professor Nicolai, the injection often leads to a fall in the blood pressure, and this may occasionally in cases of cardiac debility be very dangerous—a circumstance which deserves careful attention, because in particular cases symptoms of hypersensitivity were observed by us about the eighth or ninth day. These patients had a high temperature, reaching over 41° C., together with either (1) an exanthem resembling that of measles or scarlet fever, or (2) an enanthem causing pain in the throat (*angina*). All these symptoms disappeared in a few days, but they might signify danger in cases of weak heart.

One of the principal difficulties in the introduction of Ehrlich's dioxydiamidoarsenobenzol into medical practice has been the fear that repeated administration of it in small doses was dangerous on account of the possibility that symptoms of hypersensitivity might make their appearance. There was a similar dread of the repetition of somewhat large doses, on account of results obtained by actual experiment in cases of trypanosomiasis. Experience has proved that both of these anticipations were groundless. The case mentioned at the beginning of this article showed that the insufficient action of the first dose of 0·25 gramme—a dose which was certainly too small—could be thoroughly compensated by subsequent injections, and that no hypersensitivity ensued therefrom. In view of its immense therapeutic efficacy in general and of its failure in exceptional instances only, it may be supposed that in the latter the absorption of the remedy has been hindered by local anatomical conditions. It seems probable that pathogenic foci of this kind are more readily amenable to a reinjection with a dose varying from 0·5 to 0·6 gramme than to a single dose of greater amount; it has been found that the quantity just mentioned is in general sufficiently active. A portion of the relapses may be due to encapsulated foci of disease inaccessible to the remedy. The occurrence of relapses is unquestionable, but in my experience of many hundred cases of syphilis extending over more than six months the early relapses seem to show themselves much less frequently than under mercurial treatment. In particular they seldom take the form of an extensive recurrence of cutaneous lesions, but generally that of relapses in isolated foci, especially as plaques muqueuses in the throat, iritis, choroiditis, and paresis of the trochlearis and abducens muscles, which yield to a new injection. Whether permanent recovery has been attained or not is naturally undetermined, because the period of observation has been too short for the purpose.

The Wassermann reaction usually disappears, as has been stated by Alt, and my assistant, Dr. Lange, has found that a time from eight to 40 days is necessary to produce this effect, according to the primary severity of the reaction. In some of the cases this reaction has not reappeared so far. In five cases of absence of the Wassermann reaction in absolute lues a positive reaction appeared after the injection, to disappear again. I take such cases to be those of obscure reaction in which collections of quiet spirochætæ have been set free by the injection and have carried their specific matter into the circulation. These observations are very much in favour of a specific factor in the Wassermann reaction.

As to the technique, Iversen and Schreiber prefer the intravenous administration, which, carefully carried out, is painless, but is followed by shivering, vomiting, and pyrexia. I therefore prefer the subcutaneous administration according to the method developed by Dr. Lange and myself.

The substance No. 606 is dissolved by rubbing in a mortar with from 1 to 2 cubic centimetres of commercial solution of soda; the addition of glacial acetic acid drop by drop then throws down a precipitate in the form of a fine yellow mud which is in the next place suspended in from 1 to 2 cubic centimetres of sterilised distilled water and the fluid is neutralised by decinormal soda solution or acetic acid of 1 per cent. strength, the reaction being very carefully observed with litmus paper. The painlessness of the injections depends on the exactness of the neutralisation. We therefore centrifugalise the suspension, pour the fluid off, and afterwards make a suspension of the yellow mud in physiological salt solution. The suspension is drawn up into the syringe and slowly injected subcutaneously at a point below the shoulder-blade, the place having been previously disinfected and touched with tincture of iodine. A little pain often continues for some minutes after the injection and local lesions are not uncommon.

The new remedy, like all arsenical preparations, is an irritant and therefore often causes inflammation; this usually heals up with induration and thickening, but in some patients with sensitive tissues aseptic necrobiotic processes are set up which run a very slow course. For this reason it is desirable to perform the operation as gently as possible.

My experiences have been confirmed in every respect. It may therefore now be taken as certain that the value of the new remedy is great, nay, more, that it is indispensable, and its danger is shown to be small. Further work will make known the limits of its efficacy, but under all circumstances the discovery of it and the creation of chemotherapy form one of the greatest and happiest events in the history of the natural sciences.

THE EGYPTIAN PUBLIC HEALTH DEPARTMENT.[1]

The Budget of the Public Health Department.

THOUGH this is called an annual report, it appears from the preface that none has been issued since 1906, but we hope that Mr. W. P. G. Graham, the new Director-General, will find time to edit a similar report in succeeding years, for the work done by his officers, especially in controlling plague, must be of general interest to our readers. Unlike most spending departments of a Government service, the total expenditure for 1909—£290,190—was some £8000 less than the ordinary Budget as fixed by the Ministry of Finance. But there were in addition some special credits amounting to more than £105,000, about three-quarters of which were expended on fighting plague and rinderpest and on building a new lunatic asylum. These figures compare very favourably with the annual Budget of £60,000, which was all the Egyptian Government could afford when the first Englishman was appointed to the reformed Public Health Service in January, 1884.

Mr. Graham pays a graceful tribute to his ten divisional inspectors, whose duties are "to act in the provinces as the eyes and ears of the Central Administration." No fewer than four of these inspectors have in recent years lost their lives while in execution of their duties in dealing with diseases such as plague and diphtheria, while a fifth inspector has lately been invalided as the result of disease contracted in the course of his work in the country districts.

The in-patient and out-patient departments of the Government hospitals become more popular every year, and attention is again drawn to the inadequacy of Kasr-el-Ainy Hospital in Cairo, which is an old-fashioned building unworthy of the seat of the Medical School and of the head-quarters of the medical profession in Egypt. There can be little doubt that funds should be provided by the Government for its reconstruction. In the list of diseases notified by the medical officers of infectious hospitals and ambulance services we see that the term "typhic fevers" is used, evidently a translation from the "*fièvres typhiques*," which signifies perhaps that the Egyptian doctors are still in doubt as to whether an outbreak consists of typhus or relapsing fever or a combination of both.

Among the strange anomalies for which Egypt is famous—and it may be remembered that Lord Milner once described Government work in Egypt as a comic opera—it appears that there is no legal power to punish a medical man who gives false certificates of death. We read of a doctor who issued a certificate of the death of a person whom he had not seen, and who was proved to have subsequently recovered from his illness; the facts were reported to the legal authorities, but the action of the medical practitioner was found not to come within the provisions of the existing law!

Ophthalmia, Plague, Infectious Diseases, &c.

We have previously referred in these columns to the endeavours to cope with the all-prevalent ophthalmia in Egypt by the travelling tent hospitals, originally set on foot by the generosity of Sir Ernest Cassel, which take medical aid literally to the door of the fellaheen. The eye patients regularly treated during the year in five provincial towns amounted to more than 12,000, while more than 3000 cases of trichiasis were operated upon and cured. The eye hospital at Tanta dealt last year with nearly 5000 new cases, while 1763 major operations and 2418 minor operations were performed in the hospital, which is the direct outcome of the work done by the travelling tent hospitals. Similar eye hospitals are now being built in Assiut and Mansura partially subscribed for by the local inhabitants. One satisfactory point in connexion with this work is that more than a third of the persons attending for treatment are under the age of 15, and it is hoped that much good will be done by dealing with diseases of the eye in the various Government schools. Attention is being directed to the equally important question of infant mortality, for in the spring of 1909 the death-rate of children under the age of one year rose from a weekly average of 104 per 1000 to 654 in May and to the maximum of 700 in one week in June. The chief cause of death was summer diarrhœa, due apparently to improper food, such as melons, bread, and unripe dates, and to the all-pervading domestic fly.

The plague figures show a marked decrease, both in the number of cases attacked and in mortality, while there were only nine cases of pneumonic plague in 1909, as compared with 168 in 1908, and 250 in 1907. The general measures adopted in Egypt which have successfully kept the plague within reasonable bounds are: (1) Isolation of the sick; (2) disinfection of the persons, clothing, and bedding of "contacts"; (3) isolation of contacts in pneumonic and septicæmic cases, and of suspect contacts in bubonic cases; (4) disinfection of the field of contagion; and (5) measures against rats. During the 11 years that plague has been endemic the number of officially reported cases is 6237, of whom rather more than one-half have died. The question of inoculation against plague has again been considered, but it was felt that its general employment would be so unpopular as to make it of little value. There were 453 cases of small-pox in Cairo alone, in spite of the fact that the vaccine institute distributed more than one million units of vaccine throughout the country. Measles and diphtheria are apparently on the increase, and 8166 doses of diphtheria antitoxin were issued by the Public Health Department. There were two marked local outbreaks of enteric fever, one of which was due to a carrier, a European waiter employed in a hotel, and the other was caused by a local infection occurring in an emergency water cistern on the roof of the building.

Preventive Measures against Malaria and Cholera.

Anti-mosquito measures have been carried out to some extent in Cairo, Port Said, Suez, and Ismailia, the two latter towns having an old reputation for malaria. The report says that a mosquito campaign in Cairo and its suburbs is practically "a luxury," because malaria, yellow fever, and filariasis are almost non-existent, but the writer seems to have forgotten that dengue is often present in Cairo, and that there is much proof that this disease is conveyed by a mosquito. The malaria-bearing mosquitoes are not usually met with in Cairo except between August and November, when there is a rise of the subsoil water during high Nile. In Suez an anti-malarial society, organised by Dr. J. E. Creswell, has proved of much value. Fortunately for Egypt, when malaria arises in that country it is of the benign tertian variety, and although it would be a distinct comfort to the inhabitants to be able to dispense with mosquito curtains, as is the case in Khartum, it cannot be pretended that anti-malarial measures should occupy the chief energy of the public health officials.

The completion of the Hedjaz railway, which is utilised by pilgrims returning from Mecca, increases the anxiety of those who are responsible for the protection of Egypt from cholera. The burden falls upon the Quarantine Department in the first place and the Public Health Department in the second place. To the latter must be accorded the powers of control of possibly infected pilgrims arriving from infected countries and of submitting them to sanitary surveillance for the necessary number of days. This is essential, when it is remembered that in all the investigated outbreaks of cholera in Egypt the disease seems to have been imported there from the Hedjaz. The control of passengers at the port of arrival seems to be all-important and, when tried, has not met with much opposition. Dr. Creswell writes somewhat humorously from Suez on this point: "In the game of hide-and-seek which we annually play with the pilgrims it is well to recognise that they have the advantage of position. Any ill-advised measure which they do not like always fails, and it is to our advantage to meet their wishes in every way we can. The key to the control after their return is proper registration before they leave."

Water-supply.

The Cairo water-supply, a question which has occupied public attention in Egypt for five years, and which was referred to at length by the Special Sanitary Commissioner of THE LANCET (in June, 1909), has now received a solution. The new intake of the company has been fixed at a point below Cairo, 100 yards from the river bank, and therefore in full stream of the Nile, and four modifications of the Jewell system of filtration have been adopted. As no surface-water

[1] Annual Report for 1909 of the Department of Public Health in Egypt. Cairo. 1910. Pp. 131.

drainage or domestic sewage is to be allowed to enter the Nile the site of the intake is less dangerous than it sounds. Ever since 1884 the Public Health Department has been urging on the Government the necessity of draining Cairo, but it is only now that the work has been begun by the negotiation of several preliminary contracts.

The Jewell mechanical system of filtration has been found to be a great success in Alexandria for the last ten years, though that city is dependent upon water "derived from the Mahmudia Canal, which is probably the foulest canal in Egypt." Shone's compressed-air system of drainage has been recommended for the town of Port Said, where the subsoil water is seldom more than three feet below the surface, and where the cesspools were full of mosquitoes until the petroleum method of dealing with them was introduced.

Various Matters.

The goats of Port Said are all being examined by the agglutination test for the presence of Malta fever, and the first lot of 100 goats gave as many as 12 positive reactions. After deducting 82 people whose treatment was not continued because it was found on investigation that they had not been bitten by rabid animals, there remained 612 persons who were treated at the Antirabic Institute during the year. Of these, eight were bitten by animals proved by microscopic examination and by experiments to have rabies. The comparatively high mortality during 1908 compelled Dr. Bain, the director of the institute, to strengthen the vaccine by using material considerably fresher than that used at the Pasteur Institute in Paris, and he believes that he will have still further to strengthen it, for five of the people he treated died in spite of his efforts.

The report is enriched by six typical photographs of pellagra, a subject at which Dr. R. G. White has been working for a few months. He concludes a preliminary report as follows: "Judging from the work so far done one feels only justified in saying that at least damaged maize as found in some of the villages, and presumably used for food purposes by the poorer fellaheen, seems to cause a condition of the nature of a toxæmia. Whether this is due to some poison elaborated by a fungus growth in the grain or to the fungus itself only further research can decide." There are said to be 6500 lepers in Egypt, and it is now proposed that all beggars and vagabonds affected with leprosy should be strictly isolated, and also that certain restrictions should be made as to the occupation followed by lepers, but for all this a new law will be required.

Need of Scientific Investigation in Egypt.

There are few countries in the world that offer so attractive and untouched a field of scientific investigation as does Egypt. The most valuable asset to the land, the labourers on the soil, are decimated by the infectious diseases with which it is the duty of the department to cope, but the initial causative factors of a great many of these are still unidentified. This is the work of the Hygienic Institute, founded in 1896 by Sir John Rogers, and it would readily repay the Government to make such sacrifices as are necessary to place a work of this kind on a sound financial footing. There is no lack of useful experimental and investigational work to be done, but the work awaits a suitable series of laboratories and an adequate staff to undertake it. As the Director-General states so forcibly in his conclusions, the calling of the sanitary expert is a modern one and preventive medicine a modern science. The Egyptians are eminently a people of tradition and habit, and this fact must be taken into consideration in determining the direction in which any given movement shall advance with success. There are three measures upon which efforts should for the present be concentrated. Firstly, a sound organisation of the department upon a wide basis and the employment of Englishmen for much of the scientific and administrative work; secondly, the elaboration of a Public Health Law which shall clearly distinguish between *compulsory* regulation and optional powers granted to local authorities; and lastly, the organised extension of research work in connexion with the recognised diseases of the country, and requiring for its realisation the financial assistance of the Government.

REX *v.* CRIPPEN.

THE trial of Hawley Harvey Crippen, lately the agent in this country for the Munyon Remedies, and stated to possess in America a diploma from a homœopathic institution, who was indicted on the charge of murdering his wife Cora Crippen, known in the theatrical world as Belle Elmore, was opened at the Old Bailey on Oct. 18th and lasted five days, when on Oct. 22nd the Lord Chief Justice passed upon Crippen the sentence of death.

Mr. R. D. Muir, Mr. Travers Humphreys, and Mr. S. Ingleby Oddie represented the Crown, and the prisoner was defended by Mr. A. A. Tobin, K.C., Mr. Huntley Jenkins, and Mr. Roome.

The Case for the Crown.

Mr. Muir, in opening the case for the Crown, told the story of Mrs. Crippen's disappearance, as explained by Crippen. Inquiries from Scotland Yard led to the flight of Crippen, immediately after which human remains were found in the cellar at Hilldrop-crescent, the residence of the Crippens. Mr. Muir described Crippen's flight to Canada with Ethel Le Neve and the investigation of the headless, limbless, and boneless remains made on behalf of the Crown. He suggested Crippen's motive to get rid of his wife was that he might consort with Le Neve. Belle Elmore had totally disappeared, and Crippen, who was the only person who professed to explain the disappearance, admitted that his first account of the matter was totally false. Mr. Muir said that he would show that the mutilated remains had been dissected by a person possessed of such knowledge and skill as Crippen might be presumed to have; that there were circumstances in their appearance which made it probable that they represented the corpse of Belle Elmore; and that the remains contained a poison—namely, hyoscine—which it was known that Crippen had purchased in a large quantity.

We need not tell in detail a long and thrice-told story, but, as bearing upon the scientific evidence, which we narrate at some length, the following two things should be remembered. One of the witnesses for the Crown said that she had seen on Belle Elmore the mark of an old cut about six inches long running from the lower part of the abdomen upwards to the navel. Representatives of a firm of druggists proved that Crippen had purchased five grains of hyoscine hydrobromide shortly before the suggested date of the murder.

The Medical Evidence.

On July 14th, 1910, Mr. A. J. Pepper and Dr. Thomas Marshall visited 39, Hilldrop-crescent, and found animal remains in a hole in the cellar. There appeared to be lime mixed with the soil surrounding the remains.

Dr. W. H. Willcox on analysis found calcium hydrate and calcium carbonate in the earthy material around the remains corresponding to about 30 per cent. of quicklime. If quicklime (calcium oxide) had been mixed with soil the moisture from the soil and from the remains would turn it into calcium hydrate, and the carbon dioxide produced by putrefactive changes would turn this calcium hydrate partly into calcium carbonate, which was exactly what was found.

With the remains were found a pair of female combinations, the undervest of a woman, a man's handkerchief bearing no mark, a pyjama jacket, which was identical in pattern with a pair of pyjama trousers which were admitted by the defendant to be his. This pattern was a remarkable and unmistakeable one. Also with the remains were found three Hinde's hair-curlers containing brown hair several inches long. Microscopical examination showed that the hair was human, and roots were visible at one end indicating that probably the hair had been pulled out. The hair in curlers showed unmistakeable signs of bleaching in the distal portion. There was also some loose brown hair in the handkerchief which was lighter in colour than the other hair, presumably owing to bleaching. This showed roots at one end.

The remains were on examination found to be undoubtedly human. The heart, lungs, liver, kidneys, stomach, and intestines were typically those of a human adult. And also portions of skin and muscles of a human body were present.

The condition of the remains when found showed a

remarkable freshness and freedom from the ordinary signs of bacterial putrefaction. The heart and kidneys especially appeared perfectly fresh, and their structure could be made out quite clearly. There was a relatively considerable amount of adipocere present in the portions of skin and organs found. Bearing in mind that the remains were surrounded by soil heavily impregnated with lime it would be expected that if buried soon after death the ordinary bacterial processes of putrefaction would be delayed, since lime is antiseptic in property; on the other hand, the presence of lime would accelerate the formation of adipocere. It was after a careful consideration of the conditions under which the remains were found that Mr. Pepper, Dr. Marshall, and Dr. Willcox gave it as their opinion that they had been buried from four to eight months. From the conditions of the organs generally, and from the condition of the heart and aorta, it was concluded that the remains were those of an adult of early or middle life. The absence of marked bacterial putrefaction pointed to burial soon after death.

An examination of the remains revealed no cause of death referable to disease or injury. Among the pieces of skin with subjacent muscle found was a piece 7 inches by 6 inches. This piece had on its posterior portion a piece of muscle 4 inches in vertical extent, which corresponded exactly to the left rectus abdominis muscle. At the lower end of this muscle was a layer of tendon which was either part of the tendon of insertion of the muscle or a part of one of the transverse tendinous intersections. Also on the posterior part of this piece of skin was aponeurosis bearing the characters of aponeurosis from the lower abdominal wall. On one side of the posterior part of the piece of skin were muscles with fibres running in two directions, corresponding to the internal oblique and transversalis abdominis muscles. On the left portion of the anterior surface of the piece of skin were hairs arranged in a transverse horizontal line and corresponding to human pubic hairs.

The above characters of the piece of skin in question caused the medical witnesses for the Crown to place its position as being the lower part of the anterior abdominal wall, and the medical witnesses for the defence, Dr. H. M. Turnbull and Dr. R. C. B. Wall, assented finally to this conclusion.

On the anterior surface of the piece of skin stretching from about half an inch above the line of hairs was a mark triangular in shape, the base of the triangle being below. The width of the mark was seven-eighths of an inch below, and it extended upwards four inches. The width at the middle was half an inch and at the upper part a quarter of an inch. This mark was smooth and showed some pigmentation and transverse striation. Along the middle of the triangular mark was a slightly raised line. This mark was emphatically expressed by Mr. Pepper as being an old stretched scar. There were no stitch marks visible, but it was pointed out that these were often absent in stretched scars. Dr. Marshall, Dr. B. H. Spilsbury, and Dr. Willcox formed independently the same opinion as Mr. Pepper with regard to this mark. Stretching from the apex of the mark (scar) described was a curved mark which then extended down in a horseshoe-like manner to the left. This curved mark was stated by the witnesses for the Crown to be a groove due to folding of the skin, and they concluded that it was not a scar because this curved mark showed to the naked eye the marks of sebaceous glands and did not show the smoothness and other characters mentioned in regard to the mark described as a scar.

The medical witnesses for the defence expressed the opinion that both marks might be due to folding of skin and subsequent pressure. It was, however, concluded that while a single fold of the abdominal wall might take place it was difficult for a double fold to occur owing to the elasticity of the specimen. Also folding would not account for the triangular appearance of the portion described as a scar and which appearance was presumably due to stretching.

A microscopical examination was made of several portions of the specimen—the part described as a scar and that described as a groove. Dr. Spilsbury prepared specimens of these and the sections were examined by the medical witnesses for the Crown and by Dr. Turnbull and Dr. Wall for the defence. It was admitted by all that sebaceous glands and hair follicles were present in the groove. In the part described as a scar were—along the line of the incision in the deeper parts of the section—portions of epithelium which were mentioned in the evidence of the witnesses for the Crown as being included epidermis, which is commonly present in the scars following surgical operations. The medical witnesses for the defence stated that this included epithelium, in their opinion, might be the epithelium of sebaceous glands and hair follicles.

The jury asked to inspect the microscopical specimens, but the judge very properly advised that this be not done, since the forming of an opinion on this point involved a very considerable experience of pathological histology.

The piece of skin in question showed no sign of the navel. Mr. Pepper stated that this had probably been removed at the operation, and that it was a not uncommon practice to remove the navel when a long incision was made in the midline of the lower abdomen. Had the navel not been removed it would most probably have been present in the piece of skin in question.

All the medical witnesses were of opinion that the remains showed no certain anatomical signs as to sex.

The remains when found consisted of several portions of skin and muscle, and also the whole of the viscera of the chest and abdomen, with the exception of any pelvic viscera. The viscera of the chest and abdomen had been removed in one mass. This was considered to indicate that the person engaged had been possessed of some anatomical knowledge in the evisceration of human or mammalian animals, but it did not necessarily imply that great practical post-mortem experience was necessary.

The remains included no head nor limbs nor bone of any kind. Also no pelvic viscera were present. Thus, the certain indications of sex and identity had been most effectually removed.

The viscera (stomach, kidneys, intestines, and liver) were sent to Dr. Willcox for analysis on July 22nd. He found in each of these organs an alkaloid which produced complete paralysis of the pupil lasting several days. Cats were the animals experimented on. Dr. Willcox submitted all the organs to the Stas-Otto process and from each obtained a mydriatic alkaloid. In each case a definite purple-violet colour was given by Vitali's test, showing, in his opinion, that a vegetable mydriatic alkaloid was present—viz., atropine, hyoscyamine, or hyoscine. Having found a vegetable mydriatic alkaloid Dr. Willcox proceeded to determine which was present, and by special purification of the alkaloid obtained he found that it was not crystalline but gummy in character. Also he found that on treating a solution of the purified alkaloid with bromine in hydrobromic acid brown spheres were obtained. Hyoscyamine and atropine give crystals with this latter test, and hyoscine spheres. From these characters Dr. Willcox concluded that the alkaloid present was hyoscine.

Dr. A. P. Luff, honorary scientific adviser to the Home Office, confirmed independently the accuracy and suitability of the tests applied by Dr. Willcox, and supported him in his emphatic opinion that the mydriatic alkaloid found must have been a vegetable mydriatic alkaloid and must have been hyoscine.

Dr. Willcox found in the stomach 1/30 grain, in one kidney 1/40 grain, in the intestines 1/7 grain, and in the liver 1/12 grain; total, 2/7 grain of hyoscine, corresponding to 2/5 grain of hyoscine hydrobromide. Dr. Willcox concluded that over half a grain of the salt must have been present in the whole body.

The lungs, when submitted to Dr. Willcox, were more putrefied than any of the other organs; they showed only the merest trace of mydriatic alkaloid, very much less than any of the other organs.

The distribution of the poisonous alkaloid pointed conclusively to that of an alkaloid being administered by the mouth, and entirely excluded the possibility of the alkaloid being the result of putrefaction, since the best preserved organs yielded the greatest percentage of alkaloid.

The uses of hyoscine hydrobromide in medicine were fully considered by the Court. It was pointed out that when used internally it was generally given hypodermically in doses of 1/100 to 1/200 grain, the use being, as a rule, for cases of delirium, delirium tremens, mania, meningitis, &c., where the sedative action of the drug was required. It was also pointed out that the drug was given occasionally as a hypnotic and also in combination with morphine as a sedative. It was mentioned that sometimes the drug was given by the mouth, especially for cases of nerve disease, such as paralysis agitans, &c. Dr. Willcox stated that it was

never given by the mouth in doses of half a grain. Hyoscine is not mentioned in the British or American Homœopathic Pharmacopœias and its use in homœopathic medicine appears to be very rare, though the defendant stated that he bought 5 grains of hyoscine hydrobromide for this purpose. The defendant stated that he used in his practice two-thirds of the quantity he bought, but he could not mention a single patient to whom he had prescribed the drug. Nor could he state where the remainder of the poison was. There is no criminal case of hyoscine poisoning on record.

The Case for the Defence.

Mr. Tobin's speech for the defence endeavoured to show that Crippen was a good-natured man, that Belle Elmore's character was not above suspicion, and that the untruths which Crippen had told were intended to prevent any scandal following upon the action of his wife, who, it was suggested, was alive, while his flight was only what innocent men had done before in a panic. With regard to the medical aspect of the evidence Mr. Tobin suggested that there was a doubt as to the sex of the remains, that the mark on the piece of skin was not the mark of an operation, and that Crippen's anatomical knowledge was not sufficient to have enabled him to perform the dissection in the manner in which it had been performed. Counsel also laid stress on the fact that Crippen when obtaining the hyoscine hydrobromide need not have signed the poison book and that he openly left the record of his purchase at a shop where he was known. Crippen was then called into the witness-box and gave evidence in support of his counsel's opening. His cross-examination lasted three hours, during which time he maintained a perfectly calm demeanour. The scientific evidence for the defence has been outlined above.

The Summing-up, Verdict, and Sentence.

The Lord Chief Justice in his summing-up, after reviewing the evidence in an exhaustive and impartial manner, said if the jury were of opinion that the Crown had not completely proved their case the verdict must be "Not guilty." They must not, however, hesitate to return a verdict of guilty from any fear of what might happen in the future. If Cora Crippen was really alive there had been ample opportunity for bringing her forward. The jury after an absence of half an hour returned into court with a verdict of "Guilty." The prisoner protested his innocence, and the Lord Chief Justice in passing sentence of death warned him not to expect any remission.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE ANNUAL REPORT OF THE COUNCIL.

THE report of the Council of the Royal College of Surgeons, which is to be laid before the annual meeting of Fellows and Members on Thursday, Nov. 17th next, is now published. The report deals with the work in the various departments of the College during the year ending August 1st, 1910.

At the last annual meeting resolutions were carried (1) reaffirming the desirability of admitting Members to direct representation on the Council; (2) the amending of the Midwives Act in order that provision may be made to secure just remuneration for professional services rendered by medical men under this Act; and (3) the promotion of a new Charter and Act of Parliament to incorporate the Royal Colleges of Surgeons and Physicians of London so as to form Royal Colleges or parts of the University of London.

In its report the Council states that the resolutions were submitted to it at its meeting in December, and at the following meeting in January a special committee was appointed to consider and report on the question of the representation on the Council of Members of the College. This committee took the question into consideration and presented a report, which was considered at the meeting of the Council in March, when it was decided to take no steps with regard to this question. With regard to the proposed amending of the Midwives Act, the report states that at the meeting of the Council in December the President called attention to the report of the Departmental Committee appointed by the Lord President of the Privy Council to consider the working of the Act, and he was requested by the Council to address a letter to the Privy Council urging the need for early legislation to give effect to the recommendations of the committee. Copies of the letter addressed by the President to the Privy Council and of the letter which he received in reply are contained in the report. In reference to the proposed combination with the University of London a letter was received from the secretaries of the Royal Commission on University Education in London stating that the Royal Commission would be prepared to receive information regarding the views of the College upon questions connected with medical education in London and would like to have a statement of the nature and scope of the evidence proposed to be given. The Council appointed a committee to prepare a statement, and authorised the committee to coöperate with any committee of the Royal College of Physicians which might be appointed for the same purpose. Similar action having been taken by that College, several joint meetings of the representatives of the two Colleges were held and a report was drawn up. This report was approved and adopted by the Council of the Royal College of Surgeons in March, 1910, but when submitted to the Royal College of Physicians for approval it was referred to a committee of that College for consideration.

The by-laws relating to the admission of women to examination for the diplomas of the College have been approved by the Secretary of State for Home Affairs, and the first woman to be admitted a Member of the College received her diploma in May last.

The jubilee of the charter enabling the College to grant Licences in Dental Surgery took place during the period with which the report deals, and was celebrated by a dinner in the library of the College in December, 1909. The President was in the chair, and, besides the Vice-Presidents and Council, there were also present a considerable number of representative members of the dental profession from London and all parts of the country.

Notice having been given by the Society of Apothecaries of London of its intention to promote a Bill in Parliament to give the Society authority to grant diplomas in dental surgery, &c., and for other purposes, a petition against the Bill was lodged by the College, and in opposing the Bill the College had the support of the British Dental Association, the National Dental Hospital and College, and many of the teachers of dental surgery in London. Technical objections to the Bill were raised in Parliament on the ground that it sought to alter public Acts and that public Acts cannot be altered by means of private Bills, and it was ordered by the Speaker to be withdrawn as a private Bill.

With regard to the regulation made by the Council in June, 1909, that all candidates for the Licence in Dental Surgery of the College entering at a recognised dental hospital or school should be required to produce a certificate of having attended at a recognised dental hospital or school a course of practical instruction in the administration of such anæsthetics as are in common use in dental surgery, it seems probable, says the report, that this regulation will become general. In November, 1909, the General Medical Council adopted a recommendation to the licensing authorities that every candidate for a Licence in Dental Surgery should be required to produce a certificate that he has attended such a course. With regard to the general question of the administration of anæsthetics, the Council has had before it the text of a Bill entitled the Anæsthetics Bill, 1909, and has taken into consideration the conclusions adopted by the General Medical Council in reference to this Bill and has concurred generally with the views of that Council upon the subject.

The report contains copies of the addresses of condolence which were presented by the Council of the College to the King and Queen Alexandra upon the occasion of the death of King Edward VII., together with the replies received from the Home Secretary and from the Lord Chamberlain to Queen Alexandra. A copy of the official letter duly notifying the King's pleasure to continue to be an Honorary Fellow of the College is also included.

With regard to finance, the income of the College shows an increase of £150 on that of the previous year. There is a decrease of £480 in the receipts from the Conjoint Examining Board in respect of the Membership, but in regard to the fees received from the Fellowship, the Licence in Dental Surgery, and the Diploma in Public Health there are increases of £150, £68, and £100 respectively. Although

on account of the limited space now occupied by the Conjoint Board at the Examination Hall a decrease is shown from the amount received in the previous year from the hire of rooms account, yet a considerable sum has been realised from this source of income. The expenditure for the year shows an increase of £648. There is a decrease of £355 in the fees paid to examiners under the Board, while as regards the Fellowship, the Licence in Dental Surgery, and the Diploma in Public Health there is an increase of £83, £106, and £46 respectively. Included in the report is a full statement of the receipts and expenditure accounts.

During the year 344 Membership diplomas have been issued, together with 56 Fellowships, 84 diplomas of the Licence in Dental Surgery, and 36 Diplomas in Public Health, which latter qualification is granted jointly with the Royal College of Physicians.

The chief donations to the museum and library of the College are published in the report, and it is noticeable that in each of these departments of the College the number of visitors and readers respectively has been considerably in advance of those of the previous year.

The obituary list is a long one and is this year noteworthy as it contains the name of the late King Edward VII. The Council states that it regrets his loss the more in that he signified his approval of the creation of the Honorary Fellowship by becoming the first Honorary Fellow. The names of a past vice-president, a member of the Council, and an examiner in midwifery are included in the obituary list, together with 26 Fellows, 227 Members, and 5 Licentiates in Dental Surgery.

Full particulars are given in the report concerning the forthcoming series of College lectures, and any Fellow or Member desirous of having the report sent annually, and whose name is not already on the standing list kept at the College for this purpose, can have the same sent to them, free of charge, on applying to the secretary.

ASYLUM REPORTS.

City of Cardiff Mental Hospital (Report for the Year 1909).—At this hospital the total number of cases under treatment during the year was 873, the average daily number on the register being 673. 189 patients were admitted, and of these 181 were direct admissions. Dr. Edwin Goodall, the medical superintendent, points out that heredity of some kind was elicited in 31·2 per cent. of the admissions and that there can be no doubt that it was present in a number of cases in which no cause could be assigned. As to the "health" of the admissions, it appears that 79 were in bad health, 64 in moderate health, and 46 in good health. 119 patients were discharged. The recoveries numbered 62. Calculated upon the number admitted and excluding transfers this gives a recovery rate of 35·4 per cent. In addition to the recoveries 23 patients left relieved. As regards the duration of residence of those who left recovered, 38 out of 62, or 61 per cent., were in residence for not more than five months, and 29 out of 62, or nearly 47 per cent., for not more than four months. It is claimed that these are high percentages of short period residences in mental cases, and it is hoped that the methods employed to promote recovery are to be credited in considerable measure with these good results. Dr. Goodall points out that it is unfortunately the case that the patients discharged from the public mental hospitals are, without a due period for convalescence, plunged forthwith into their usual avocations, these often being associated with mental stress. In these circumstances it is perhaps astonishing that relapses are not more frequent. There were 81 deaths, and necropsies were held in 75 cases. Judging from the amount of research work done it would appear that much use is made of the excellent laboratory provided by the wisdom of the committee of visitors.

Dorset County Asylum (Report for the Year 1909).—At this institution the average daily number on the registers was 847. 173 patients were admitted. The medical superintendent, Dr. P. W Macdonald, gives a table showing in tabular form the number of persons admitted and the number resident at the end of each year during the quinquennium ending with the close of 1909 He points out that though the figures show a greater variation in the number of admissions than in those resident, the true criterion of variation in the rate of increase or decrease of lunacy should not be based on the admissions, for it frequently happens that persons are admitted who are not reliable factors in computing a table of annual increase. In this class must be reckoned many of the senile, who after a few weeks or months of nursing are fit to return home. Dr. Macdonald raises a question whether it is reasonable that the ratio of the insane to the population should be raised by the inclusion of cases which could have been equa ly well cared for elsewhere, but which because of the difficulty of providing for home care are sent to the mental hospital. Taking first admissions only, it appears that there is a clear 50 per cent. in which there were present maniacal symptoms. This is different from the proportion obtaining a few years ago, when cases of this type were considerably fewer than those in which depression was the main characteristic. Fewer cases of general paralysis and epileptic insanity were admitted. Dr. Macdonald observes that among the causes of insanity the influence of heredity is steadily assuming larger proportions. The percentage of recoveries among those discharged was 40·28. On the female side the percentage of recoveries for the year was 57, whereas among the men it was only 24. The death-rate, calculated on the total number under treatment, was 7·1. Dr. Macdonald reports on the successful results of treating recent cases in the solaria instead of in bedrooms or dormitories.

Hereford County and City Lunatic Asylum (Report for the Year 1909).—The average daily number resident was 505, and 586 persons were under care during the year. 86 patients were admitted. It is very remarkable that as an associated cause of insanity thyroid disease in one or other of its several forms was noted in 16·6 per cent. of the males and 63·4 per cent. of the females. 50 patients were discharged, the percentage of recoveries calculated upon the number of admissions (transfers from other asylums excluded) being 28. The deaths numbered 40, giving a percentage calculated on the daily average number resident of 7·9. Post-mortem examinations were held in 76·5 per cent. of the total number of deaths.

East Sussex County Asylum, Hellingly (Report for the Year 1909).—The average daily number of patients on the register was 1092. There were admitted 277 persons. The proportion of senile cases was higher than in the previous year, while the number of patients suffering from general paralysis was considerably less. 11 patients were admitted with the latter disease, and in only 4 of these could a history of syphilis be obtained, and of these but 2 showed the stigmata of the disease. The number of patients discharged was 191, of whom 108 were recovered, the recovery rate being 43·37 per cent. on the direct admissions. Deaths during the year numbered 98, the death-rate being 8·97 per cent. on the total number under treatment. The mortality from tuberculosis is low, being at the rate of 10·9 per 1000. Dysentery caused only one death. Post-mortem examination was made in 71·5 per cent. of the deaths. The medical superintendent, Dr. F. R. P. Taylor, reports that in 247 of the 277 direct admissions a family history was obtained and that heredity was ascertained in 28 per cent. of the males and 43 per cent. of the females. In Dr. Taylor's opinion it is most important to impress on the public the hereditary nature of mental diseases and to supervise most carefully the education of children who have, through their parents, a tendency to the disease.

Roxburgh, Berwick, and Selkirk District Board of Lunacy (Report for the Year ending May 15th, 1910).—The average daily number resident in the asylum at Melrose was 312·6. The number of admissions during the year was 52, or 20 less than during the previous year, and 14·2 less than the average for the ten previous years. 34 patients were discharged, and of these 23 had recovered, and 11 were relieved. The recoveries as compared with the admissions gave the proportion of 44·2 per cent., the recovery rate for the previous 37 years since the opening of the asylum having been 33·7 per cent. The deaths numbered 23, giving a rate of mortality, calculated on the average number on the register, of 7·1 per cent. The average rate for the previous 37 years was 7·3 per cent. Post-mortem examinations were held in 78·2 per cent. of the deaths. Pulmonary tuberculosis was found to be present in an active form in 34·7 per cent. of all the deaths.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Liverpool.—The annual report of Dr. E. W. Hope, the medical officer of health of this important city, with its population of some 760,357, is always interesting reading. The birth-rate of Liverpool is considerably above the average of the large towns, and although the rate is declining in common with that of the country as a whole, it is still exceeded by only two towns having a population of over 100,000. The general death-rate for the year 1909 was 18·3 per 1000, and in connexion with this rate Dr. Hope draws attention to the fact that the proportion of deaths which take place in Liverpool in public institutions is larger than is the case in other towns. Generally speaking, this phenomenon implies poverty and want, but, as he points out, it may also, and no doubt does, indicate that the institutions have a wide reputation and attract people both from within and without the city. This latter is certainly an increasingly important factor, and with the improvement of infirmaries it will be necessary to be very careful in drawing inferences as to the prevalence of poverty and want from the popularity of these institutions. But whether this be so or not, some 34·3 per cent. of the total deaths in Liverpool take place in Liverpool as compared with 25·8 per cent. in Manchester, 16·9 per cent. in Leeds, and 23·9 per cent. in Birmingham. Small-pox was introduced into the city on six separate occasions during 1909, the disease being ship-borne in three instances and introduced by overland Russian emigrants in three instances. As regards protection against this disease Dr. Hope remarks that the medical inspection of school children is showing that there is growing neglect of vaccination, and that the younger children manifest less satisfactory vaccination than the older ones. It was found that in one Poor-law district nearly 14 per cent. of the children newly admitted to school were unvaccinated. Presumably in referring to less satisfactory vaccination than formerly Dr. Hope has meant vaccination by one mark instead of four, and if this be so it seems a pity that the names of those responsible for the vaccinations cannot be given, as no medical man has any right to administer what is practically an underdose of a drug, serum, or vaccine. With respect to scarlet fever, a chart is furnished showing the death-rate from this disease in Liverpool during the past 60 years, and Dr. Hope adds that for the first half of this period at intervals of a year or so the number of deaths from scarlet fever reached proportions which would now be regarded with astonishment. But from the period when hospital isolation was provided, and better administrative methods adopted, there has been a remarkable drop in the death-rate from this disease, and he thinks that this lesson may be applied to other forms of infectious diseases, such as whooping-cough and measles. An expression of faith in the utility of isolation hospitals coming from a great city such as Liverpool is an important fact and will be welcomed by a large number of medical officers of health. The statement would, however, prove of even greater value if all the data upon which this conclusion is based could have been given, since the scepticism so often expressed by medical officers of health as to the value of isolation, especially in scarlet fever, renders it necessary that this question shall be freely discussed. On p. 48 there is furnished a table showing the death-rate from scarlet fever for each 10-yearly period from the year 1856 to 1905, and the rates given in this table do not seem to fit in with the table on p. 269 in such a manner as to quite justify Dr. Hope's inferences. It would certainly much assist investigation of this very important subject if, from the standpoint of his exceptional experience, he would discuss the matter in more detail in his next annual report or by means of a separate report. Dr. Hope has, we are glad to see, a very firm faith in the value of isolation hospitals, and he predicts that isolation for a limited number of cases of whooping-cough will lead to some diminution of the disease. In connexion with the subject of tuberculosis some very reasonable comments are made in reference to the limited degree of infectivity of the disease. In Dr. Hope's view forms of tuberculosis other than phthisis may be regarded as practically non-infectious, the large majority of the cases of phthisis coming under the same category. As regards the remainder they are, he adds, infectious only under circumstances favourable to infection, and have little, if any, tendency to spread where reasonable precautions can be adopted. He observes that in the great consumption hospitals of the country, notwithstanding the constant exposure of the attendants on the sick, infection is extremely rare, and the same remark may, he says, be made with reference to the Liverpool Hospital for Consumption and to Poor-law institutions. It is, in his opinion, the vicious domestic or living conditions which lie at the root of the evil, and it is against these that sanitary effort in Liverpool has been directed. Dr. Hope then furnishes an interesting account of the work done in the direction of destroying the breeding-places of tuberculosis by the Liverpool Housing Committee, which has now 2200 dwellings with 8075 people under its control. These dwellings have been erected on the sites of the insanitary dwellings which they replaced, and are reserved for the people dispossessed; that is to say, the people whose slums were demolished form no less than 80 per cent. of the total inhabitants. Although this is the case the phthisis death-rate in the new dwellings is only 1·9 per 1000, a rate which is considerably below that of the districts in which the dwellings are situated. With respect to this administrative action Dr. Hope thinks that "no practical sanitarian would suggest that if, instead of spending the money in demolishing the slums, purchasing the sites, and erecting the dwellings, it had been spent in providing sanatoria and in removing and maintaining the diseased people therein, that the results would have been at all comparable either in benefit to the city or to the inmates of the dwellings themselves." It may be added to this statement that 50 beds have been set apart at one of the isolation hospitals for the treatment of cases of tuberculosis. As regards the question of tuberculous milk an instructive chart is furnished showing that under the local powers conferred by the Liverpool Corporation Act, 1900, in connexion with the examination of milk furnished from outside the city, there has been a progressive decline in the percentage of samples found to be tuberculous, but the photographs of some of the country cowsheds on farms which supply milk to the city show that there is still much work to be carried out before a pure milk-supply can be ensured. The quality of the water supplied to Liverpool as indicated by daily bacteriological examination shows that the average number of bacteria has been only 23 per cubic centimetre, that B. enteritidis sporogenes was absent in all cases, and that bacillus coli was only found in 50 cubic centimetres and 100 cubic centimetres of the water. This is a most valuable and interesting report for which we wish to thank the author.

Borough of Sunderland.—The population of this borough reached the estimated number of 159,157 in 1909. The birth-rate was 29·4 per 1000 and the death-rate 17·0 per 1000. The number of women living at child-bearing ages is estimated at 40,252, and the number of children born per 1000 of such women was 116 in the year 1909. There were 229 cases of diphtheria notified and the fatality rate was 14 per cent., and Dr. Henry Renney strongly urges parents to seek medical advice in throat diseases in children, however slight the malady may appear. A localised outbreak of diphtheria occurred in 1909, and the medical officer of health was inclined to ascribe it largely to the fact that the children attacked were in the habit of playing about a sewer ventilator. Since June, 1901, there have been 81 patients treated in the Stanhope Sanatorium as patients of the Sunderland corporation, and of these 46 are dead, 11 well, 8 fairly well, 11 cannot be traced, 1 is ill, and 4 are still in the sanatorium. Of the 46 who died after leaving the sanatorium the average duration of life after discharge was 2 years 2 months. The corporation grants certificates to farmers who comply with the regulations as regards air-space and cleanliness and who keep only cows which have yielded negative results with tuberculin. An interesting observation was made with respect to a farmer who clipped the tails and hind-quarters of his cows and groomed the animals daily, with the object of lessening the amount of pollution, with the result that samples of milk which before this practice showed bacillus coli to the extent of 10,000 per cubic centimetre, subsequently yielded only 10 bacilli coli per cubic centimetre. Tubercle bacilli were found in 7·4 per cent. of the total number of samples of milk examined in 1909.

Plympton St. Mary Rural District.—The council of this district has for several years sent tuberculous patients to one of the Devon sanatoriums, and Mr. S. Noy Scott observes as a

result of his experience that a comparison of the cases sent to the sanatorium with those who remained at home has not yet convinced him that sanatorium treatment leads to such good results as some persons believe. He does not, he says, wish to belittle the great good which sanatoriums have done in impressing upon the public the enormous value of fresh air, good food, and rest in the treatment of phthisis, but he enters a protest against placing an undue reliance upon expensive treatment in these sanatoriums when the fresh air, good food, and rest can be obtained at home. In his judgment the cases occurring amongst the working-classes treated at home live as long as those treated elsewhere. But, of course, it has to be borne in mind that as regards urban communities the fresh air cannot be obtained at home, nor is it easy to carry out a proper course of living without the control secured at sanatoriums.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7933 births and 4213 deaths were registered during the week ending Oct. 22nd. The annual rate of mortality in these towns, which had been equal to 12·8 and 13·1 per 1000 in the two preceding weeks, declined again last week to 13·0. During the first three weeks of the current quarter the death-rate in these towns averaged 13·0 per 1000. In London the death-rate during the same period, calculated on the probably over-estimated population, did not exceed 12·6 per 1000. The lowest reported annual death-rates last week in these 77 towns were 6·2 in King's Norton, 6·3 in Hornsey, and 7·2 in Walsall and in Handsworth; the rates in the other towns ranged upwards to 19·3 in Wigan, 19·7 in Merthyr Tidfil, 19·8 in Brighton, and 21·4 in Middlesbrough. In London the reported death-rate last week did not exceed 12·6 per 1000. The 4213 deaths from all causes registered in the 77 towns last week showed a decline of 48 upon the number returned in the previous week, and included 504 which were referred to the principal epidemic diseases, corresponding with the number in the previous week; of these 504 deaths, 296 resulted from diarrhœa, 75 from measles, 42 from diphtheria, 37 from whooping-cough, 28 from enteric fever, and 26 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these diseases in the 77 towns last week was equal to 1·6 per 1000, against 1·5 and 1·6 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Leyton, Coventry, Ipswich, Warrington, or in six other smaller towns; the annual death-rates therefrom ranged upwards, however, to 4·1 in Southampton, 4·2 in Grimsby, 4·9 in Burnley, 5·3 in Bury, and 7·5 in Brighton. The deaths attributed to diarrhœa in the 77 towns, which had declined in the seven preceding weeks from 527 to 296, were again 296 last week; the highest annual rates from these causes in the 77 towns last week were 2·9 in Middlesbrough, 3·0 in York, 3·6 in Brighton, and 4·4 in Burnley. The 76 fatal cases of measles showed a further marked increase upon recent weekly numbers, and caused the highest annual rate of 3·6 per 1000 in Brighton. The deaths referred to diphtheria, which had been 42 and 34 in the two previous weeks, rose again to 42 last week, of which 15 occurred in London and its suburban districts, 3 in Southampton, and 2 both in Reading and in Stoke-on-Trent. The 37 fatal cases of whooping-cough showed a further decline from the numbers in recent weeks; they included 9 in London and West Ham, and 3 in Manchester and in Sheffield. The deaths referred to enteric fever, which had been 38, 21, and 43 in the three preceding weeks, declined again last week to 28, of which 4 were returned in Plymouth and Devonport, 3 in Manchester, and 2 in Birmingham. The 26 fatal cases of scarlet fever were 7 below the number in the previous week, but included 4 in Stoke-on-Trent and 2 in Barry. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased in the nine preceding weeks from 1423 to 1745, had further risen to 1792 on Saturday last; 231 new cases of this disease were admitted to these hospitals during last week, against 249, 245, and 234 in the three preceding weeks. The 1176 deaths from all causes in London last week included 194 which were referred to pneumonia and other diseases of the respiratory system, showing an increase of 32 upon the number in the previous week, and exceeding by 10 the corrected average number in the corresponding week of the five years 1905–09. The causes of 23, or 0·5 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London (and in its eight suburban districts), Manchester, Leeds, Bradford, Newcastle-on-Tyne, and in 49 other smaller towns; the 23 uncertified causes of death in the 77 towns included 3 in Birmingham and in Gateshead, and 2 each in Liverpool, Leicester, St. Helens, Warrington, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 821 births and 470 deaths were registered during the week ending Oct. 22nd. The annual rate of mortality in these towns, which had been equal to 14·4 and 12·9 per 1000, in the two preceding weeks increased slightly to 13·0 in the week under notice. During the first three weeks of the current quarter the death-rate in these eight towns averaged 13·4 per 1000, and exceeded by 0·4 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 8·4 and 12·4 in Leith and Aberdeen, to 15·6 in Dundee and 16·8 in Perth. The 470 deaths from all causes in the eight towns last week exceeded by 2 the number returned in the previous week, and included 47 which were referred to the principal epidemic diseases, against 83, 69, and 63 in the three preceding weeks; of these 47 deaths, 25 resulted from diarrhœa, 13 from diphtheria, 4 from whooping-cough, 3 from "fever," and 2 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·3 per 1000, the rate from the same diseases in the 77 English towns being 1·6 per 1000. The deaths attributed to diarrhœa in the Scotch towns, which had been 51, 40, and 29 in the three previous weeks, further declined last week to 25; they included 10 in Glasgow, 4 in Edinburgh, in Dundee, and in Paisley, and 2 in Greenock. The 13 deaths referred to diphtheria showed a decline of 2 from the number in the previous week; 5 occurred in Dundee, 4 in Glasgow, and 3 in Perth. The fatal cases of whooping-cough, which had been 8 and 10 in the two preceding weeks, declined to 4 last week, of which 2 were returned in Glasgow. The 3 deaths referred to "fever" included 2 fatal cases of enteric and 1 of cerebro-spinal meningitis; 1 each occurred from enteric in Aberdeen and Paisley, and the fatal case of cerebro-spinal meningitis in Glasgow. The 2 deaths from scarlet fever occurred in Greenock and Perth. The deaths referred to diseases of the respiratory system in the eight towns, which had been 72 and 69 in the two preceding weeks, increased to 80 last week, but were 4 below the number in the corresponding week of last year. The causes of 10, or 2·1 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·5 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 619 births and 384 deaths were registered during the week ending Oct. 22nd. The mean annual rate of mortality in these towns, which had been equal to 15·9 and 16·9 per 1000 in the two preceding weeks, further rose to 17·4 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these Irish towns averaged 16·7 per 1000; the mean rate during the same period did not exceed 13·0 in the 77 largest English towns and 13·4 in the eight principal Scotch towns. The annual death-rate during last week was equal to 20·7 in Dublin, 16·0 in Belfast, 15·8 in Cork, 8·4 in Londonderry, 5·5 in Limerick, and 29·2 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 17·0 per 1000. The 384 deaths from all causes in the 22 town districts last week showed a further increase of 10 upon the numbers returned in the two preceding weeks, and included 42 which were referred to

the principal epidemic diseases, exceeding by 11 the number in the previous week; these 42 deaths were equal to an annual rate of 1·8 per 1000, the rate from the same diseases last week in the 77 English towns being 1·6, and in the eight Scotch towns 1·3. The 42 deaths from these epidemic diseases in the Irish towns last week included 20 from diarrhœa, 5 from measles, 5 from whooping-cough, 4 from enteric fever, 3 from diphtheria, 2 from typhus, and 1 from scarlet fever, but not one from small-pox. The 20 deaths attributed to diarrhœa exceeded the number in the previous week by 4, and included 8 in Dublin, 8 in Belfast, and 2 in Londonderry. The 5 fatal cases of measles occurred in Belfast, and the 5 of whooping-cough in Dublin. Of the 4 deaths from enteric fever 2 were returned in Dublin and 2 in Sligo; and the 2 fatal cases of typhus occurred in Dundalk. The deaths in the 22 towns last week included 63 which were referred to pneumonia and other diseases of the respiratory system, against 44 and 66 in the two preceding weeks. The causes of 5, or 1·3 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·5 per cent., while in the Scotch towns it was equal to 2·1 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: F. Bradshaw to Chatham Dockyard, and F. D. Lumley to the *Warrior;* T. Austen to Bermuda Hospital and Dockyard, and F. J. Burns to the *Vernon*. Staff-Surgeons: E. R. L. Thomas to the *Victory*, additional, for disposal; E. O. B. Carbery to the *Calypso*. Surgeons: G. F. Syms to Malta Hospital; F. R. Featherstone to the *Exmouth;* and J. H. Wright to the *Vivid*, additional, for disposal; G. Nunn to the *Shearwater*, additional, and to the *Shearwater*, on recommissioning; and R. H. McGiffen to the *Halcyon*, additional, for the *Leda*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Colonel M. W. Kerin, C.B., principal medical officer of the Bareilly, Garhwal, and Dera Dun Brigades, has been appointed to officiate as Principal Medical Officer of the Seventh (Meerut) Division during the absence on leave of Colonel F. B. Maclean. Lieutenant-Colonel R. R. H. Moore has been appointed to the Medical Charge of the Military Hospital at Bulford Camp, Salisbury Plain. Lieutenant-Colonel A. F. Russell, C.M.G., commanding the Military Hospital at Malta, has arrived home on leave. An exchange on the roster for service abroad has been sanctioned by the War Office between Lieutenant-Colonel C. Birt and Lieutenant-Colonel R. H. Hall. Lieutenant-Colonel J. M. Irwin, on vacating his appointment as assistant director of medical services, has embarked for a tour of service in North China. Lieutenant-Colonel R. W. Wright, from Shoeburyness, has been posted for service in the Eighth (Lucknow) Division. Lieutenant-Colonel G. F. Gubbin, from Colaba, has been reverted to the home establishment. Lieutenant-Colonel G. H. Barefoot has been selected for the command of the Station Hospital at Ranikhet. Major T. J. Lenehan, having notified his intention to retire from the service, has had his name removed from the roster for service abroad. Major W. Hallaran has been posted to the Northern Army, India, for duty in the Third (Lahore) Division. Major C. M. Fleury, from Tidworth Park, has embarked for a tour of service in South China. Captain W. C. Croly, from Colchester, has taken over charge of the Military Hospital at Ipswich. Captain H. E. M. Douglas, V.C., on completion of his course of instructon at the Royal Army Medical College, London, has been posted to Woolwich. Captain E. V. Aylen has been appointed Specialist in Dermatology and Venereal Diseases to the First (Peshawar) Division. Captain J. du P. Langrishe has been transferred from Poona to Mhow. Captain W. F. Tyndale, C.M.G., has taken over duty in the Dublin District. Captain W. W. Browne has been posted to Colchester and appointed a Specialist in Health Efficiency and Medical Adviser on the Gymnastic Staff. Captain F. G. Garland, from Conway, has joined at Manchester. Captain C. D. Myles and Captain M. C. Beatty have been posted to the Southern Command from the Royal Army Medical College. Captain S. B. Smith, on completion of duty at Ticknock Camp, has joined at Dublin. Captain R. J. Franklin, Captain R. M. Ranking, Captain T. S. Coates, Captain D. Ahein, and Captain J. H. Duguid, on completion of their promotion course in London, have been appointed to the Cork District. Lieutenant H. V. B. Byatt has been transferred from Khandalla to Poona. Lieutenant F. W. M. Cunningham, from Donard Camp, has taken up duty at the Curragh. Lieutenant H. G. Robertson, from Sheffield, has joined at Derby. Lieutenant C. M. Nichol, from Colchester, has been appointed to the medical charge of the Military Hospital at Weedon during the absence on leave of Captain W. R. Douglas.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel F. C. Reeves, of the Madras Establishment, has been permitted to revert from civil to military employment. Lieutenant-Colonel R. E. S. Davis, Bombay, has arrived home on leave from India. Major T. H. Symons has embarked for India. Major A. Gwyther, civil surgeon at Saran, has been appointed a Civil Surgeon of the First Class in India. Major J. H. McDonald has been selected to act as Deputy Sanitary Commissioner of the Southern Registration District during the absence on privilege leave of Major C. R. Bakhale. Captain E. C. Hudson has been appointed Officiating Health Officer at Simla, vice Captain H. M. Mackenzie, who has taken over the chair of Physiology in the Medical College, Calcutta, during the absence of Captain D. McCay on furlough. Captain M. Mackelvie, officiating civil surgeon of Puri, has been appointed to act as Civil Surgeon of Darbhanga. Captain G. C. L. Kerans has been appointed Specialist in Ophthalmology to the Eighth (Lucknow) Division. Captain W. F. Brayne, special plague medical officer, Pegu Division, has been granted three months' privilege leave. Captain P. K. Tarapore has been appointed to officiate as Superintendent of the Mandalay Central Jail during the absence on leave of Captain A. W. Greig. Captain H. W. Pierpont has joined the Central Provinces and has been posted to Chanda as Civil Surgeon. Captain A. S. Leslie has been appointed as Superintendent of the Insein Central Jail in place of Captain H. H. G. Knapp transferred. The services of Captain C. A. Sprawson and Captain W. Lapsley have been placed permanently at the disposal of the Government of the United Provinces. Lieutenant A. M. Jukes, in charge of the Brigade Laboratory at Shillong, has been appointed a Specialist in the Prevention of Disease.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank: George H. Stevenson, Eben S. B. Hamilton, and Leopold T. Poole. The undermentioned to be Lieutenants (on probation): Cadet-Sergeant Charles John Simpson, from the Belfast University Contingent, Officers Training Corps (dated Sept. 10th, 1910); Aubrey Gardner Brown (dated Sept. 10th, 1910); and David Turnbull Richardson (dated Sept. 30th, 1910).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Welsh Border Mounted Brigade Field Ambulance: Lieutenant Douglas C. L. Orton to be Captain (dated Sept. 15th, 1910).

For attachment to Units other than Medical Units.—Frederick George Harper to be Lieutenant (dated August 12th, 1910).

Attached to Units other than Medical Units.—Lieutenant John Aitken to be Captain (dated Sept. 15th, 1910). Lieutenant Arthur L. B. Green resigns his commission (dated Oct. 26th, 1910). Captain William Moreland Haladay Spiller, Royal Army Medical Corps, to be an Adjutant of a School of Instruction (dated Oct. 12th, 1910).

DEATHS IN THE SERVICES.

Lieutenant-Colonel Robert Anderson, R.A.M.C. (retired), on Oct. 24th, at Bury St. Edmunds. He entered the service in 1868 as assistant surgeon, became surgeon in 1873, surgeon-major in 1880, and reached the rank of lieutenant-colonel in 1888, and retired in 1893. He served in the Egyptian War of 1882, when for part of the time he was in medical charge of the right wing of the Ismailia Palace Hospital (medal and Khedive's Star). He was elected Mayor for Bury St. Edmunds in 1907.

Correspondence.

"Audi alteram partem."

CAN FISH CONVEY THE BACILLUS OF CHOLERA?

To the Editor of THE LANCET.

SIR,—In an annotation under this heading last week you refer to Professor Gosio's researches into the question, the results of which will certainly be awaited with interest.

In the meantime may I say that when a borough medical officer of health I used to make careful inquiries into all the possible channels of infection of typhoid fever when cases were notified, and, among other things, into the question of ordinary cooking fish. In two or three instances in which a cook was the only patient in the house, I could not trace any evidence of infection by water, watercress, shell-fish, flies, contact with suffering patients or carriers, &c. I formulated the theory that infection had possibly been conveyed by fish caught in undoubtedly polluted waters, or which had lain on the stall of a fishmonger who was a vendor of doubtful shell-fish, and that the cook had received infection from the fish, which had been infected either directly in polluted waters or indirectly by the fishmonger handling first, say, polluted infected oysters, and then, without washing his hands, handling the fish. It generally seemed more probable that the fish had *imbibed* infection directly from the polluted waters. I accounted for the fact that the cook was the only person in the household to develop typhoid fever because she handled and *gutted* the fish, while other members of the family only partook of the fish after it had been gutted, cleaned, and either boiled or fried in boiling oil or other grease. I imagined that the cook's hands had become infected by the fish in the raw state and that she had then conveyed infection (typhoid bacilli) to her mouth by unwashed hands. I think this mode of infection both for typhoid fever and cholera and allied diseases (paratyphoid, diarrhœa, &c.) is not only possible but actually does occur occasionally, but I also think it is only occasionally. In other words, I think ordinary fish from polluted waters have in my experience actually been the vehicle of infection; but at the same time I consider it a comparatively rare means of transmission limited only to those who handle and prepare fish in the uncooked state, and amongst these only to a comparatively small proportion who neglect to wash their hands after such handling or preparation and inadvertently suck their fingers or carry other food to their mouths with unwashed hands. Of course, were the fish not properly gutted or cooked other persons might suffer also.

I am, Sir, yours faithfully,

Norwich, Oct. 24th, 1910. J. T. C. NASH.

BODY METABOLISM IN CANCER.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 1st appeared a report by a committee of the British Association upon the body metabolism in cancer. Acting upon an assumption that the onset of malignancy has an intimate relationship with diminished or perverted function of the reproductive organs, the liability to the malady waxing as the reproductive activities wane, the committee has treated inoculated mice (which sex?) with spermin and orchidin, and with fresh testicular emulsion and extract. The physiological principle involved in the experiments is that the internal secretions of reproductive organs may exert some restraining and coördinating influence upon the growth of somatic tissue elements. Now Beatson and others tried oöphorectomy—accompanied by the administration of thyroid extract—in human mammary cancer; and the results, such as they were, proved the supposition that the internal secretion of the ovaries encourages the mammary cancer. Thus there are two opposing principles serving as a basis for treatment. On the one side it is hoped to retard malignant growth, arising presumably from any epithelial tissue, by the supply of sexual secretions; on the other it is hoped to retard malignant growth arising from a secondary sexual organ, by the withdrawal of such a secretion. But can the committee be sure that the substances used will produce their effect as internal secretions acting directly upon the growths and not in other capacities?

It has been suggested that spermin plays the part of a catalytic ferment which regulates oxidation in the tissues, as witness its use in obesity. And therefore it may have a general effect as a ferment upon the blood serum, and in this way induce conditions unfavourable to malignant growth. Leucocytosis may be expected to follow the administration of organ extracts, and almost certainly of spermin. To induce this state has long been a purpose in treating cancer, though seldom or never has there been more than temporary amelioration. Leucocytosis may not be a factor in the committee's experiments, but it is worth noting that the varied results given in the report are just what one expects with leucocytotic agents.

I would remark that the possible effect on the metabolism of the serum exercised by leucocytes receives hardly any attention. They are unicellular glands, and speaking generally and without reference to a particular kind, an agent that increases their number and probably also their activity may thus indirectly alter the metabolic balance of the serum. And this is one of the channels through which we hope to combat malignancy.—I am, Sir, yours faithfully,

W. T. GIBSON, A.R.C.S.

Newcastle-upon-Tyne, Oct. 23rd, 1910.

A POINT IN PHARMACOLOGY.

To the Editor of THE LANCET.

SIR,—Senile flatulence is a complaint both common and difficult to cure, especially in persons who are not constipated. Some time ago I noticed the good effect produced by powdered cloves given by an old nurse after my fluid preparation of the same spice had failed. I saw that the spirit of cloves was absorbed in the stomach but that the woody fibre passed on to the seat of the complaint. Acting on this, I procured from Messrs. Oppenheimer and Co. some 5-gr. capsules of powdered cloves coated in keratine. They acted admirably and I recommend their trial. I think there are other drugs which might be used in a powder and keratine coated—e.g., assafœtida. Aloes and assafœtida might be given in keratine instead of as a pill, also ferrum redact. in gastric ulceration. I think we might well revise our B.P. pill list and replace many of them by keratine-covered powdered drugs.

I am, Sir, yours faithfully,

Pontrilas, near Hereford, Oct. 24th, 1910. L. L. THAIN.

THE EDUCATION OF THE STUDENT OF MEDICINE.

To the Editor of THE LANCET.

SIR,—I have read Professor Howard Marsh's admirable and thoughtful address to the students at Leeds, and I think every teacher at hospitals ought most seriously to consider Professor Marsh's suggestions and impress more upon the students the cardinal points in their lectures, and not to enter into so much of the minutiæ, comparatively not so important. Of course, this cannot be done unless the different examining boards are willing to take these suggestions into consideration and vary their questions accordingly. No doubt this is a matter that ought to be well considered by the various governing bodies, and it is well worth the attention of the whole profession. So many students now fail at the examinations through the examiners insisting on their answering correctly minor and unimportant questions.

I am, Sir, yours faithfully,

West Cromwell-road, S.W. W. CUNNINGHAM CASS.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—A general meeting will be held at 11, Chandos-street, Cavendish-square, on Nov. 3rd, at 4.30 P.M., when Mr. R. Denison Pedley will read a paper on "The Care of Teeth in School Children." Dr. Stanley Colyer and others will take part in the discussion.

SANITARY PROGRESS AT COPENHAGEN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

ASTRIDE between the Baltic and the North Sea, Copenhagen claims yearly an increasing number of visitors. Commercially it is of even greater importance on account of the enormous quantity of Danish butter shipped from Copenhagen and consumed in Great Britain. And we also receive a considerable amount of bacon and of meat—notably beef—from Denmark. Therefore, whether by reason of the numerous tourists who visit the country or of the foodstuffs we receive from Denmark, we have a direct interest in the sanitary administration of Copenhagen. Here the cattle are killed for exportation, here the butter and bacon are stored, and here our tourist and holiday folks land. Under these circumstances, it is satisfactory to know that, in respect to sanitary administration and legislation, Denmark is fully entitled to a place among the most progressive nations. Indeed, in some respects she has taken the initiative in giving a good example. Thus it was in Denmark that the compulsory notification of infectious diseases was first enforced. A law to this effect came into operation as far back as 1861. In regard to tuberculosis, Denmark is again in advance. The notification of tuberculosis has been rendered compulsory since 1905. Further, it should be noted that practitioners have to report all the cases they treat so that the town authorities may know what diseases are prevailing and what is the general state of health; but the reports need only give the names and addresses of infectious cases. If this is not done, and the service is gratuitous, the medical practitioner may be punished, so that medical service is not unduly rewarded.

Fresh Fish.

The medical staff attending to all health matters in Copenhagen has its headquarters at the town-hall and is under the direction of Dr. E. M. Hoff, who is Dean, or, as we should say, chairman, of the Royal Health Council of Denmark. To Dr. Hoff I am indebted for much of the information I am able to give and for most courteous and helpful advice. Altogether there are nine medical officers attached to the municipal services and two veterinary surgeons. Of course, the medical staff consults with the engineering staff in regard to questions of drainage, water-supply, &c. In this latter respect I may say that great satisfaction is expressed. The water-supply from artesian wells is ample and is believed to be quite pure. Formerly the sewers fell into the sea by numerous outlets at the nearest convenient points. In 1892 a general sewerage scheme was planned and subsequently carried out. This consisted of building a main collecting sewer along the whole shore-line. At a certain point an outfall from this main sewer was constructed so as to convey the sewage to a distance of two kilometres from the shore out into the open sea. Thus there is no longer any contamination of the harbour or the sea front. This not only puts an end to the nuisances that used to arise, but enables boats full of live fish to come close to shore and right into the town by means of the salt-water canals. In this manner at least the smaller fish are kept alive till the moment they are sold. Any number of wooden boats are pierced with holes and filled with fish; these boats just float on the surface of the water, and the living fish is taken out of them when wanted. But as everyone cannot go to the water's edge to buy fish, there are water tanks on wheels and the live fish is brought to the doors of the people's houses. Never before have I been in a town where all the fish, whether cheap or dear, is so beautifully fresh. The principal fish market was built by the municipality and is let to a wholesale fish salesman. It is a delight to see how clean and bright these premises are kept. There is no spreading the fish on slabs so that dust and dirt may settle on them. Very pretty tessellated tile tanks are filled with running water, and here the smaller fish swim about. The larger fish, such as cod or halibut, are too cumbersome to keep alive, and are therefore placed in the cold-storage rooms.

A Technical School for Servants.

Not only are the fish fresh, but they are generally very well, sometimes even artistically, cooked. At Copenhagen it seems to be understood that good food badly cooked is apt to be disappointing. In any case the domestic servants' trade union has instituted a school where members of the union are taught how to be clean and neat, how to sew, to wash and starch, but, above all, how to cook. A little restaurant is attached to this school where anyone can have a cheap meal, thus giving the pupils an opportunity of exercising their art. The trade union, while insisting that a good servant shall earn from 25 to 30 kroner (a krone equals 1*s.* 2*d.*) per month and pay half a krone subscription to her union, does at the same time endeavour to render her fully competent to accomplish her work. Also, by providing sleeping accommodation, it helps to prevent servant girls falling into bad company or suffering undue hardships when out of employment. It is a pity, however, that the sleeping rooms are not more spacious. The law insists on a minimum of 300 cubic feet per bed, and the dormitories I visited barely gave more than this very scant allowance. This perhaps does not much matter in summer when the windows can be kept open, but in winter they are shut and there is no other means of ventilation. Nevertheless, this servant girls' school and home is an admirable institution, and it is all the more likely to succeed in turning out competent students of domestic economy as it is due to the initiative of the servants themselves and not to patronage coming from outside their own ranks.

Cooking at Sea.

In the same way there is an old frigate moored in a canal close to the most fashionable centre of the town. Here there is a school for ships' cooks. On board a ship with the limited space such as prevails at sea young cooks try their 'prentice hands at making dishes such as are served to passengers on sea voyages. There is an awning on the deck, tables are laid out, and numerous inhabitants of Copenhagen take their meals there, for they are both varied and inexpensive. Thus fully qualified cooks are being prepared for the sea, and it is not necessary to point out that, whether at sea or on shore, efficient cooking not only adds to the joys of life but is a very necessary aid to digestion. In this respect, just as travellers on the Mediterranean endeavour to obtain a berth in an Austrian-Lloyd steamer because of the superior cuisine on that line, so connoisseurs bound for Copenhagen and the Baltic seek to secure a passage on the *Titania* of the Finland Line. Not only is she comfortably furnished, but the chef is renowned among epicures. The 20 or so *smörgasbords*, or appetisers, placed at the disposal of the passengers before meals are marvellously and wondrously prepared. To pick and choose amidst this variety of stimulating flavours should suffice to provoke an appetite even among the most jaded and recalcitrant dyspeptics. As for the ordinary and robust traveller, it means that he will not fail to "eat through his ticket," as the Americans say.

Cheap and Wholesome Bread.

Of far more importance, however, than these delicacies are such articles of primary necessity as bread and meat. It has always been a matter of the greatest difficulty to maintain a high standard of purity in the food-supply. Nor is this entirely the fault of unscrupulous tradesmen. The purchaser is for ever clamouring for cheapness and is too apt to patronise those who lower their prices without inquiring at what sacrifice this reduction is achieved. In this never-ceasing conflict of interests between the purchaser and the tradesman some impartial umpire is needed to regulate market prices. At Copenhagen those who were in the greatest need of some such protection have themselves succeeded in creating the necessary check. It was during the years 1884 to 1886 that the exaggerated charges made for bread brought matters to a crisis. The organised workmen succeeded in borrowing 4000 kroner and established a small coöperative bakery, where they made pure wholesome bread and sold it among themselves at a price that would just pay the cost of production. Thus they produced much better and cheaper bread than the bakers. The enterprise grew. To-day the assets of the bakery are estimated at half a million kroner. To deliver the bread 30 horses and 19 carts are necessary. Fifty-three persons are employed at the bakery and are paid the highest wage in the trade. They work for only eight hours a day and have a week's holiday per year with full wages while away. The bakery is provided with a bathing-room and cloak-room, so that the journeymen bakers can wash thoroughly

and change their clothes before beginning work. The most recent machinery is employed, and next to the bakery stand vast flour mills. Thus not only is a further economy realised by grinding their own grain, but the coöperators know exactly what sort of flour they are using. When I visited the mill I found the millers were mixing Danish rye with small Russian and large German rye so as to secure a good medium flour. The wheat they use for the most part comes from America. Looking at all this from the health point of view the benefit is twofold. First, the bread made is more clean and wholesome, and this example has served to raise the standard of quality throughout the trade. Then the competition has compelled a general lowering in the price of bread. Though the cost of the raw material has greatly increased of late years and higher wages are now paid, nevertheless the price of bread is lower than it was before the coöperative bakery was established. The yearly turnover is about 700,000 kroner, and this is sufficient to steady the prices of the whole trade.

Meat, Milk, and Beer.

The coöperators' next step was to turn their attention to the meat-supply, and they have succeeded in establishing a business which by competition also helps to lower and to check the price of meat throughout Copenhagen. They send their own buyers to the cattle market and then conduct the animals bought to the municipal slaughter-house. After slaughter the meat thus obtained is sold in four well-appointed shops. Altogether a meat business equal to an annual turnover of 300,000 kroner has been established entirely in the public interest.

In regard to the milk-supply the workers have not done so much to influence the general market. A great reform in the milk trade has been achieved, and this I hope to describe at length, but it was not due to the initiative of the workmen's coöperative societies. Nevertheless, there is a large workmen's coöperative milk-supply society. At the town-hall, where all the milk is analysed, I was told that the milk of the coöperative society was very good. This workmen's organisation, after 12 years of existence, now employs 128 grown-up persons and 230 boys to assist in delivering the milk. They sell 8,000,000 litres of milk and 85,000 kilogrammes of butter per annum.

Finally, we have the workmen's coöperative brewery which has an establishment worth 259,966 kroner, employs 150 persons, and sells so much beer that it requires 31 horses and 16 carts to deliver it to the customers. On visiting this brewery I was able to verify that the bottles and casks were properly sterilised before they are used. There is a portable electric light which can be put inside the casks to see that no foreign object is within and that they are quite clean. Though the brewery seemed to me satisfactory I could not find anything new. The workers were better paid, and that should help to keep them in better health, but no attempt was made to demonstrate that the beer was purer, more nutritious, less narcotic, or that it was in any other way superior to the beer sold in the ordinary trade. One thing, however, was insisted upon—namely, that they brewed a very large quantity of what is called anti-alcohol beer. Like many other temperance drinks—ginger-beer, to wit—it does contain some alcohol, but only 1½ per cent. per volume. The other beers brewed are pilsener at 3 to 3½ per cent. of alcohol, lager at 4, and stout at 5 per cent. of alcohol. Considering that mild English ales very frequently contain more than 8 per cent. of alcohol, all these Danish beers may be considered, if not temperance, at least very temperate drinks. But the great point is that we have here an institution which supplies beer to a large section of the population and which has no interest to serve in adulterating this popular beverage.

Higher Standard of Life and Lower Mortality.

While the food-supply of Copenhagen has been improved by the competition of the coöperative societies and the prices have been kept down, the air-supply has also been ameliorated. The sea-front, as already explained, is no longer contaminated by sewage. Within the city some of the worst slums have been pulled down. Streets have been widened and the extension of business in the centre of the town has converted the sites of former slums into offices and warehouses. At the same time the town council has been buying up land in the outskirts and laying out new districts for habitation. The night inspection of lodging-houses has become more rigorous and new sanitary by-laws are in contemplation to render such control still more severe. The system of poor relief has been improved and the various funds that give out-of-work allowances have received subventions from the municipality. Thus with better sanitation, less overcrowding, pure water, cheaper, less adulterated food, higher wages, shorter hours of labour, and more generous relief for cases of distress the health of Copenhagen has greatly improved of late. Last year the death-rate only amounted to 14 per 1000, but it would be unfair to take this exceptional figure; it would be nearer the mark if the average general death-rate is estimated at about 15 per 1000. The infant mortality is also a good indication of the sanitary and social conditions of a town. The average mortality within the first year of life, from 1882 to 1886, was 17·6 for the legitimate and 35·3 for the illegitimate infants, making a total of 21·1 per 100 born. The average percentage from 1902 to 1906 was 12·8, 20·3, and 14·4. While last year among the legitimate infants the percentage of deaths was only 9·4, among the illegitimate it was 15·5, making a total of both legitimate and illegitimate of 10·9 per cent. The same satisfactory story may be recorded concerning pulmonary tuberculosis. In 1870 the deaths amounted to nearly 400 per 100,000 of the population. Without any fluctuation the fatalities from this disease have decreased every year till in 1908 they had fallen to 145 per 100,000.

Abolition of the Contagious Diseases Act.

By the side of these successes there is one measure that does not give much good promise. In 1906 the Contagious Diseases (Women) Act was abolished. It is true that other and even more drastic regulations were introduced, but the result is very doubtful. At the same time that the examination of public women was abandoned it was decided to enforce severe punishments for anyone, whether man or woman, who could be convicted of infecting a person. To-day if a man complains to the police that he has been infected by a woman the police can arrest the woman, force her to be examined, and if it can be proved that she knew she was infected she will be criminally convicted. The authorities provide printed forms to all medical practitioners, and they are advised to give these forms to their patients. Till such patients receive a certificate that they are cured it is a criminal offence to have sexual intercourse. Punishment is inflicted under Clause 181 of the Penal Law of Feb. 10th, 1866, which is a sort of codification of former laws. The clause in question says:—

> If anybody who knows or supposes he or she has venereal disease has sexual connexion with another he or she will be punished with simple imprisonment or, under special conditions, with hard labour.

Thus, not long ago a scandal was occasioned by the arrest of a young man who belonged to a good family. He had seduced and infected several girls, and was therefore condemned to three years' hard labour, not for seducing but for infecting his victims. On the other hand, while thus menaced with severe penalties, all those who are infected have every opportunity provided of getting cured. The town council has appointed and pays 12 medical practitioners to attend gratuitously on any man or woman suffering from venereal disease. At first these medical men were paid 3 kroner (or 3*s.* 6*d.*) for the first visit and 1 krone for the subsequent visits, but now they are paid a regular salary of 2000 kroner per annum. They earned much more under the former method of payment. The present system consists, therefore, of facility of treatment on the one hand and severity of punishment on the other, but it seems altogether insufficient. Where poverty is the cause of prostitution it does not provide the money needed, nor does it take into consideration that the victims, however they may suffer, naturally shrink from denouncing those by whom they have been contaminated. In any case, the results obtained are not encouraging. It may justly be said that the statistics do not extend over a sufficiently long period to form a definite opinion, but so far as they go they are not favourable. Three years have elapsed since the freedom of prostitution was proclaimed and I give the figures for the three years preceding 1906 and the three years following. Before the new law the number of cases of gonorrhœa per 10,000 of the population of Copenhagen was 125, 115, and 114. In 1906, the year of transition,

there were 112 cases; and in the three years following, when the new law was in force, there were 129, 142, and 132 cases. With regard to venereal sores, there were 11 per 10,000 of the population for each of the three previous years, 18 during the year of transition, and 17, 26, and 23 for the years 1907-08-09. Now, the most important figures, those that relate definitely to syphilis, are scarcely less discouraging. The cases of syphilis per 10,000 inhabitants for the three years preceding the new law were 43, 30, and 32, during the year of transition 33, and during the three years following 45, 56, and 49.

It does seem as if among the many successful things done and described above, we have in this last attempt at reform a measure that gives every promise of failure.

(To be continued.)

THE RECENT ARMY MANŒUVRES IN THE SOUTH OF ENGLAND.

(BY A SPECIAL CORRESPONDENT.)

THE annual training of the military forces, which has only recently concluded, furnishes many particulars of more than ordinary medical interest, as the numbers of men employed and their association with army reservists, special reservists, and the Territorial Force has been the first attempt made by the War Office to test the working of Mr. Haldane's new scheme of army administration.

General Arrangements.

The summer training for the majority of the regular forces commenced in August in various localities. During the first weeks in September these troops were more or less concentrated under divisional control of their divisional commanders and employed as such. From Sept. 15th to 17th the 3rd and 4th divisions assembled for inter-divisional manœuvres in Somersetshire at concentration camps. Army manœuvres on a large scale followed, and these took place in the vicinity of Salisbury between Sept. 19th and 24th. Camp equipment was taken on the usual manœuvre scale, two blankets and one waterproof ground sheet per man being carried in the second line of transport. Each unit was provided with one of the new filter water-carts drawn from the mobilization equipment. The dress worn by all regimental officers and men was drill order service dress, the directing staff alone wearing blue undress uniforms (patrol jacket) and black leather leggings and ankle boots. No restrictions were placed by the general officer commanding-in-chief (Lieutenant-General Sir C. W. H. Douglas, K.C.B.) on any of his troops entering public-houses. He published an order reminding all ranks that the inhabitants of the districts in which the training and manœuvres took place would in future judge the army by the conduct and bearing of the soldiers whom they met during the manœuvres, and that it was therefore in the power of the troops to bring credit or discredit on their units and on the service to which they belonged. It is satisfactory to record that the behaviour of the troops was excellent. March discipline was also satisfactory and was strictly observed as being of the highest importance in the interests of efficiency and for the avoidance of unnecessary fatigue to the men. The following rules were enforced:—

1. Cavalry and mounted infantry were not allowed to march along a road more than four horses abreast, particular care being taken to leave a space clear at one side for other traffic.

2. Infantry were not allowed to march more than four men abreast, including commanders and supernumeraries, the left side of the road being followed. In the event of men who were marching on the extreme left of the road being caused greater inconvenience than the others, after each halt the left-hand man of each section of fours was placed on the right when the march was resumed.

Regimental arrangements were made for the supply of beer and mineral water in casks for the troops on arrival in camp. No mineral water in bottles was allowed. The sale of beer was limited to one quart per man per diem and issued under strictly controlled regimental arrangements. Sergeants' messes and canteens were not allowed.

Sanitary Arrangements.

Sanitary detachments were detailed by each unit, as laid down in war establishments, and were placed at the disposal of the officers in medical charge of units. A proportion of each regimental sanitary detachment was detailed to accompany the advance party of the unit proceeding to fresh camping grounds in order to prepare latrines and urinals and have them ready for the troops when they marched into camp. All latrines were on the short trench system, each trench being 3 feet long by 1 foot wide and 1 foot deep and placed 2 feet 6 inches apart. When camps or bivouacs were occupied for more than one night an additional depth was excavated according to the number of days the camp was likely to be occupied. 2 per cent. of trenches were laid down as sufficient for one night and 5 per cent. for longer periods. Urine trenches or pits were dug as part of the latrine system alongside the latrines. All latrine and urine trenches were filled in before the camps or bivouacs were vacated and their sites carefully marked so that other units which might subsequently occupy the ground could avoid them, the turf which was carefully cut being properly replaced. Orders were issued that trenches were not to be dug round the tents or for cooking purposes to avoid disfigurement of the ground and thus avoid claims for compensation. Before leaving camps and bivouac grounds all rubbish, such as empty preserved-meat, milk, and other tins, bottles, hay bands, &c., were collected in heaps near the margin of the camping-ground, and after burning were left ready for subsequent removal; burial was not permitted. Manure from the transport lines was removed to separate sites on the boundary of camping-grounds and left there for the occupier of the land on which the troops encamped. A senior officer was detailed by the officer in command of troops at each camp or bivouac to remain behind until after the departure of the troops, to see that camps and bivouac grounds were left thoroughly clean and fit for immediate occupation by other troops should occasion arise.

The places at which water for the men to drink and wash at, as well as water for horses, were marked by distinguishing flags or notice boards by the Royal Engineers, after selection by the sanitary officers. No water was allowed to be used for human consumption except water that had either been filtered in the service filter water-carts or that drawn from the standpipes of town supplies. Sentries were placed over the watering places and were given written orders as to their precautionary duties. Washing in horse troughs was forbidden. One non-commissioned officer or a private of the Royal Army Medical Corps trained in water duties was detailed to supervise the working of each filter water-cart; he was assisted by a private detailed by the unit concerned.

Camps and bivouacs occupied for more than one night were as a rule hired; other camps occupied by troops within the manœuvre areas were taken up under the provisions of the Manœuvre Act of 1897.

Food-supplies.

As far as possible the food-supplies and the transport services were carried out under active service conditions, the responsibility for the same being delegated to the commanders of the divisions. The manœuvre ration counted from midnight to midnight and consisted of (1) meat, ½ pound fresh and ½ pound preserved; (2) 1 pound bread or ¾ pound biscuit; (3) grocery ration, supplied from Woolwich; and (4) contractor's, haversack and vegetable ration.

The ½ pound preserved meat was eaten for breakfast and the ½ pound fresh meat ration for dinner. In addition to the above, ½ pound of preserved meat was issued on the same day as the rations for Sept. 15th for use as an iron ration. Rations (including grocery, haversack, and vegetable ration) and forage ration were issued each evening for the next day's consumption and were carried as follows:—

(*a*) On the man:—1. 1 pound of bread or ¾ pound biscuit (less the portion consumed at breakfast). Every two men, 1½ pounds of wood in the form of a bundle of sticks 10 inches to 12 inches long, and 1 pound preserved meat (in a tin called the iron ration). The iron rations (½ pound of preserved meat per man) were issued in 1 pound tins and were only to be consumed under the orders of the company commander in the exceptional case of the cook's wagon not reaching the men. When so consumed the fresh meat cooked for dinner was to be eaten by the man in lieu of ½ pound preserved meat at breakfast the next morning. Under ordinary circumstances

the 1 pound preserved meat current ration was consumed at breakfast. 2. Grocery ration:—

⅝ ounce tea.
2 ounces sugar.
½ ounce salt.
} Woolwich ration, each in separate packets.

3. Haversack ration, for midday meal:—

4 ounces biscuit.
2½ ounces cheese.
} Contractor's ration.

(*b*) In the cook's wagon (which formed part of the first line of transport):—

4. Camp kettles and butcher's implements.

½ pound fresh meat per man.
8 ounces potatoes ,,
1 ounce margarine ,,
2 ounces onions ,,
⅛ tin condensed milk ,,
⅛ ounce pepper ,,
1½ pound fuel wood ,,
} Contractor's vegetable ration.

The price of each grocery ration was fixed at ¾*d.* and the cost of the haversack and vegetable ration 3¼*d.* per man. The men were charged at the rates they pay for messing in barracks, any balance being defrayed from the Regimental Institute funds.

Units were in possession of second line transport sufficient to carry one day's supply of bread, meat, groceries, forage, and fuel wood. These supply wagons were replenished from the transport and supply columns, which also carried one day's supplies complete. Each unit had distinguishing flags on all their vehicles provided regimentally. Tents were not as a rule used during the actual process of operations.

(To be continued.)

RECENT OUTBREAKS OF PLAGUE IN THE NEAR EAST.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Plague in Jeddah.

THE epidemic, or annual revival, of plague in Jeddah, described in my letters to THE LANCET of April and May last, came to an end early in May. One fatal case occurred on the 4th of that month, and none subsequently. A fresh revival of the disease must, however, be anticipated in the coming winter. It may be noted in connexion with the internal sanitation of Jeddah and the other towns of the Hedjaz, in regard to the deficiencies of which repeated representations have been made to the Turkish Government for many years past, that an effect has at last been produced. That Government has created a special Commission or Council to deal with the question, and is taking steps to obtain the necessary funds for improving the sanitary condition of those towns.

Plague in the Yemen.

It will be recalled that plague appeared in the port of Hodeidah in April; that down to April 30th, 31 cases, with 24 deaths, had occurred there; and that between April 30th and May 5th, 8 further cases, with 5 deaths, were reported. Between May 5th and 17th there were 6 more cases; on the 17th and 18th 2 fatal cases; and on the 20th 1 case, also fatal. Finally, on June 10th it was stated that no fresh case had occurred for 15 days, and the measures in force on arrivals from Hodeidah were suppressed. The disease also appeared in three neighbouring villages.

Plague in Bushire.

An outbreak of plague occurred in Bushire and its neighbourhood in the spring and early summer of this year. The first case was seen in the village of Zulmabad, near Bushire, on March 28th; its nature was confirmed bacteriologically, and on the 31st Bushire was declared infected. The returns for the following weeks were as follows:—Weeks ending: April 2nd, 3 cases, 1 death; April 9th and 16th, 0 cases, 0 deaths; April 23rd, 4 cases, 2 deaths; April 30th, 4 cases, 3 deaths; May 7th, 12 cases, 8 deaths; May 14th, 7 cases, 6 deaths; May 21st, 5 cases, 6 deaths; May 28th, 17 cases, 13 deaths; June 4th, 3 cases, 3 deaths; June 11th, 3 cases, 1 death; June 18th, 3 cases, 2 deaths; June 25th, 1 case, 1 death. On July 1st Bushire was declared plague-free. The above cases and deaths were distributed as follows: In Bushire itself, 30 cases, 22 deaths; in Zulmabad village, 23 cases, 16 deaths; in Jabri village, 2 cases, 2 deaths; in Mahmudabad village, 3 cases, 3 deaths; in Reshire village, 4 cases, 3 deaths. There were in all 62 cases and 46 deaths. I am indebted for the above details to Captain C. B. McConaghy, I.M.S., chief quarantine officer in the Persian Gulf, who also adds that the rumour that the infection came to Bushire from Bahrein (where plague had been prevalent in the preceding year) was entirely unsubstantiated; that there was no increase in the numbers of or mortality among rats—these animals appearing to play no part in this outbreak; that a certain number of cases occurred among the *sarbazes*, or soldiers of the Persian regiment in garrison; and that there were the usual difficulties in dealing with plague among an ignorant and superstitious population. There was also nothing to show definitely that the infection came from India, and Captain McConaghy does not think it did, though he gives the following details, which seem to point to such a possibility: "Two days before the man Haidar (the first known case) was seen his wife had died. She had been visiting and also helped to nurse a fellow villager who had died some seven to ten days before. This villager was the sister of a coolie who used to work cargo on the Bombay and Persian steamers and had also died some days previously."

Plague at Basra.

A few cases of plague in man were, it will be recalled, seen at Basra at the end of April and beginning of May, and at the same time several infected rats were found and killed. On August 9th 3 fresh cases of the disease, with 2 deaths, were reported, all occurring in the same house in Basra; and a little later it was stated that the third patient had also died, and that a large number of dead rats had been discovered in the same quarter of the town. No further cases were recorded, and on August 23rd Basra was declared plague-free.

Plague in Odessa.

On May 22nd (June 4th) the attendant in a night-refuge in Odessa was found to be suffering from plague; he was removed to a municipal hospital, where he died on the 26th (June 8th). For the following 40 days no further cases were seen, but on July 6th (19th) a baker occupying a shop in the same quarter of the town as the night-refuge fell ill with the disease. Four days later his assistant was attacked; both slept in the bakery. On July 5th (18th) a girl, aged 16, employed in an adjoining restaurant, had died, and a bacteriological examination showed that she had died from plague. Dead rats were found on that and the adjoining premises, the floors of which were taken up and burnt. On July 13th (26th) a Jewish boy was admitted to the Jews' hospital. On July 20th (August 2nd) a case was seen in a sailor on a ship arriving at Odessa from Nikolaief. Cases continued to occur in Odessa through July and a great part of August. In all, between May 22nd and August 18th (Old Style) 77 cases of plague, with 19 deaths, were registered. There had been rumours of the existence of the disease in the government of Bessarabia, at Kief, and Nikolaief, but the Russian authorities have declared officially that the suspicious cases there were in every instance shown by bacteriological evidence not to have been cases of plague. The origin of the outbreak in Odessa was unknown, but it was thought that the infection had been brought by rats on shipboard from Alexandria. It may be noted that among the measures put in force in Odessa were the following. Every householder was compelled, under a penalty of three months' imprisonment or a fine of 300 roubles (£30), to have from one to three rat-traps, according to the size of his premises, and to set and bait them in accordance with the instructions issued by the authorities. Squads of municipal rat-catchers were formed. A reward of 10 roubles (£1) was offered to anyone reporting an undoubted case of plague. The last occasion of a plague outbreak in Odessa was in 1902, when (as also in 1901) a small number of cases of the disease were seen there.

Plague in the Kirghiz Steppes.

A small outbreak of plague in the Kirghiz Steppes of the Astrakhan government occurred in June and July last. Four villages in the Narynsk and Kalmuck portions of the Steppes

were infected. Between June 13th and 25th (June 26th and July 8th) 13 cases and 12 deaths were registered. A number of medical men were sent to the infected centres; anti-plague inoculation was, it is said, employed to a considerable extent; and on July 8th (21st) the Astrakhan government was officially declared plague-free.

Plague at Beirût.

On Sept. 29th an imported case of plague was seen at Beirût. The patient was a sailor on a coasting steamer, the *Syria*, which arrived, without passengers, from Alexandria on Sept. 27th. The ship had lain for 20 days in Alexandria, where sporadic cases of plague continue to occur, and there can be little doubt that the infection was contracted there.

Plague at Adalia.

On Sept. 21st (Oct. 4th) it was reported that a sweetmeat-seller in Adalia had been found to present symptoms of plague; he had been ill for three days. Next day a second case was seen. There seems little doubt that both were cases of plague. It will be remembered that each year since 1905 (included), with the sole exception of the year 1907, isolated cases of the disease have been seen in Adalia, and usually about the same period of the year.

Constantinople, Oct. 10th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Conferment of Degrees.

THE new buildings are gradually becoming incorporated in the working University machine. It is true that the laboratories are not yet completely furnished, but some rooms are in use, and the Council was able to meet for the first time in the 1910–11 session in the room designed for that purpose in the new wing. The first Congregation of the University for admission to degrees was held on Oct. 20th at the Victoria Rooms. The city was reminded that this ceremony was about to take place by a procession through the streets of students in various costumes, starting from the University and returning by a circuitous route to the Victoria Rooms. The hall was absolutely full, admission being by invitation only. At the front of the platform sat the Vice-Chancellor and other officers of the University, the Deans of Faculties, the Lord Mayor and the Sheriff, and the Master of the Merchant Venturers' Society. Behind these was a large concourse of students, armed with various wind instruments, banners, and the other paraphernalia of the young barbarian. In front of the Vice-Chancellor was an open space to which those about to receive degrees were ushered; on his right sat the Council of the University, on the left the Senate, and on either side behind these the rest of the University staff. The remainder of the hall was filled with onlookers, members of the court, members of the city council, and others. At the back of the hall was another body of students. The honorary degree of D.Sc. was conferred on Professor C. Lloyd Morgan, who, as first Vice-Chancellor of the University, principal for over 20 years of University College, Bristol, and professor of psychology, has done great things for Bristol. That this is recognised was shown by the conferment upon him of the only honorary degree given at this the first graduation ceremony; by the eulogistic address with which he was introduced by Professor F. R. Barrett to the Vice-Chancellor; and by the tremendous ovation with which he was greeted. It was unfortunate that an otherwise dignified ceremony should have been to some extent spoilt by the students' interruptions, which would have been pardonable and even welcome had they been more conspicuous for quality of wit and less so for volume of noise.

The Association of Alumni.

The members of this association dined together on Oct. 21st at the Imperial Hotel, Clifton. Ladies were included in the company, which consisted not only of members of the association but also of many of the University professors and lecturers. In addition to the toast of "The King," proposed by Mr. G. Munro Smith, the President of the association, who was in the chair, the health of the University of Bristol was proposed by Dr. R. Shingleton Smith, whose recollections of the foundation of University College, Bristol, showed that it was largely due to the energy of those medical men who were in charge of the Bristol medical school before the College existed, and who felt that in enlarging their school its scope should be widened to include other branches of higher education. Sir Isambard Owen, the Vice-Chancellor, replied on behalf of the University, insisting especially on the pre-eminent need for men, and not for buildings or money only. The next toast, that of the guest of the evening, Sir Oliver Lodge, was proposed by Professor G. H. Leonard. Sir Oliver Lodge, in reply, showed points of similarity between the origin of the University of Birmingham and that of Bristol. The health of the association was proposed by Professor I. Walker Hall, and Mr. Munro Smith, in his reply, reminded his hearers that the objects of the association were to bring together past and present students of the University and to maintain a record of their careers. Letters from Sir William Ramsay and others regretting absence were read, and songs were contributed by Mr. F. H. Rose and Mr. A. M. Tyndall.

The University Settlement.

At a meeting held in the University on Oct. 21st, the Lord Mayor of Bristol presiding, Sir Oliver Lodge gave a most interesting address to a crowded audience. Speaking of the social problems of the twentieth century, he said that society should not be allowed to stratify; it should be stirred up. He did not consider that the work of a settlement lay in dealing with the "absolute dregs" of society so much as in preventing their precipitation by a scientific study of the causes underlying it. He spoke of the efforts made in Birmingham to provide means for such study and for the training of persons in social service, efforts which were leading to the formation of a school of practical economics. He insisted upon the importance of giving a definite training to those persons who would in the near future hold administrative posts under the reformed Poor-law and the like. A statement recently circulated among those interested says that the University Settlement in Bristol has in view the promotion of the general welfare in its own neighbourhood and the provision of a centre for social study and training. The committee in charge of the scheme recommends that temporary premises should be acquired, and that the building of a settlement with club-rooms, &c., should be delayed until some more definite idea of the shape and scope of the work has been arrived at. For immediate purposes £1500 are required to buy and equip premises in East Bristol; the maintenance will cost from £300 to £400 annually. Already over £720 have been subscribed or promised.

Bristol Eye Dispensary.

At a committee meeting of this charity held on Oct. 11th the resignation of Dr. A. Ogilvy was accepted with much regret. Mr. E. H. E. Stack was elected to the vacant post of full surgeon, and Dr. A. Fells, Mr. W. P. Taylor, and Dr. H. B. Porteus were elected assistant surgeons.

Scarlet Fever and Hospital Accommodation.

The need for a large increase in the accommodation available in Bristol for the reception of cases of infectious disease is being forcibly illustrated. Scarlet fever is prevalent in the St. Philip's and St. George's districts to such an extent that cases cannot be admitted into the city hospitals. Reference was made in this column a fortnight ago to the shortage of beds at the fever hospitals, and this outbreak has proved that expansion is a matter of urgent importance. The health committee has asked Dr. D. S. Davies, the medical officer of health, to report as to the necessary steps by which the situation may be temporarily relieved.

Phthisis in Bristol.

The Bristol board of guardians, after prolonged discussion of a scheme for purchase of a country estate near Bristol to be utilised as a sanatorium for pauper consumptives, has determined to confer with the health committee of the city council before taking any steps in the matter. The health committee has of late been exercised as to the inadequacy of accommodation for Bristol consumptives in the beds available for that purpose at the Winsley Sanatorium; so that a conference between the two bodies comes at a particularly fortunate moment and will, it is hoped, result in an adequate and coördinate scheme for the treatment of patients suffering from phthisis.

John Davies, M.R.C.S. Eng., L.S.A.

Mr. John Davies died at his residence, 8, Beaufort East,

Bath, on Oct. 10th, in his seventieth year. He received his medical education at the Birmingham Medical School and took the "College and Hall" qualification in 1863. After holding the appointment of house surgeon at the Stockport Infirmary Mr. Davies entered the Indian Medical Service and was for some time civil surgeon at Balasore. He retired from the service about 1870, when he commenced practice in Bath, and in 1872 was elected medical officer for the Walcot district of the Bath union, which appointment he only resigned last year. Mr. Davies was senior surgeon to the Bath lying-in charity. He was a good sportsman and a frequent follower of the Duke of Beaufort's foxhounds. By his death one of the oldest and best known medical practitioners has been removed from Bath, and much sympathy is felt there for his widow.

Fatal Accident to a Medical Man.

At the Bradford-on-Avon (Wilts) police court on Oct. 20th a domestic servant was charged with the manslaughter of Mr. Richard Thompson Cæsar, M.R.C.S. Eng., L.S.A., at Limpley Stoke. Evidence showed that the accused was riding a bicycle without a light about 7 P.M. on Oct. 7th. She did not sound a bell, and in the dark ran into the deceased, who was walking in the middle of the road. Mr. Cæsar sustained a fracture of the base of the skull and died in consequence on Oct. 17th. An inquest was held on Oct. 18th, when a verdict of "Accidental death" was returned, and the coroner, at the request of the jury, severely reprimanded the woman. After hearing the evidence the magistrates remanded the accused, on bail, for eight days. Mr. Cæsar, who was 73 years of age, resided at Bearsted, Kent, and was on a visit to Limpley Stoke. He was formerly surgeon to the Wellington Dispensary, Shirley Children's Hospital, and the Downton Cottage Hospital. Mr. Cæsar was at one time surgeon-colonel in the 2nd Volunteer Battalion of the Hampshire Regiment, and he had also been President of the Salisbury Medical Society.

Proposed Medical Officer of Health for Cornwall.

At the last meeting of the Cornwall County Council a discussion took place in reference to the proposed appointment of a medical officer of health for the county. The joint committee had previously recommended the sanitary committee to suggest such an appointment to the county council, and had mentioned a salary of £500, rising to £600 per annum. The sanitary committee, whilst recommending the council to adopt the joint committee's resolution, had proposed a reduction of the salary by 25 per cent. After some discussion, in which the chairman of the sanitary committee (the Hon. John Boscawen) stated that he was not in favour of the proposed reduction, it was decided, on the motion of Sir Arthur Quiller-Couch, to recommend the finance committee, as the authority which decides the question of the remuneration, to fix the salary as £500, rising to £600. It is satisfactory that the county council has adopted this course, as, after all, the proposed salary is quite small enough for such a position as medical officer of health for Cornwall.

Oct. 25th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

St. Mary's Hospitals.

THE old St. Mary's Hospital and the Southern Hospital threw in their lot together some years ago and a new hospital in place of the Southern was erected near the present infirmary buildings in Oxford-road. Unfortunately, however, the funds did not allow of the opening for patients of this well-appointed hospital for the diseases of women and children. Now, however, there is to be a benefaction of £2000 for the endowment of two beds in the gynæcological wards, given by Mr. Edward Hopkinson in memory of his father and mother, to be called the John Hopkinson and Alice Hopkinson beds. Mr. Edward Hopkinson's benefaction is, however, conditional on the hospital being opened for the reception of patients within six months' time. This offer, therefore, is a challenge to the well-wishers of the hospital and to the benevolent of Manchester which, it is to be hoped, will be responded to generously.

Housing in Hulme.

A public meeting was held in Hulme on Oct. 18th to consider whether a large area, formerly occupied by cavalry barracks, should be devoted to the building of houses or converted into an open space. Hulme is densely populated, so that an open space—a lung in popular phraseology—would in itself be a good thing. But, on the other hand, houses for working people are urgently needed. The corporation has in other parts of Manchester gone to great expense in the building of what the people for whom they were intended call "barracks." Now the working people of Manchester do not like barracks, euphemistically called "tenement" houses. As one of the speakers said, "They want houses, not warehouses." All these ventures into providing dwellings for the poor add to the burdens of the ratepayers, for they have always been a loss to the corporation. The people want cottages at a rent of from 3*s.* to 5*s.* a week. It is acknowledged that the corporation could only build such houses at a loss, but that does not alarm these dwellers in Hulme, so they passed a resolution unanimously to the effect that the corporation should "without delay" build houses on the barracks street site in accordance with the intention for which the land was purchased. Such is the pleasant prospect which opens out before the gaze of ratepayers, sanitary committees, and corporations.

No Mortuary at Crewe.

At a recent inquest at Crewe Dr. E. C. Bailey drew attention to the undesirability of making post-mortem examinations at private houses. In the present case his task had been very unpleasant, there being so many children about the premises. The foreman of the jury said it was equally unpleasant for the juries. Finally, the jury recommended the coroner to write to the Crewe corporation asking them to provide a mortuary. It is strange that in an important and growing town like Crewe a mortuary was not provided long ago.

Oct. 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Research Defence Society.

AT a meeting of the Edinburgh branch of the Research Defence Society held in Edinburgh on Oct. 21st an address was given by Mr. Stephen Paget, F.R.C.S. Eng., on Pasteur's Life and Work. Lord Dunedin occupied the chair, and among others on the platform were Sir John Batty Tuke, Sir A. R. Simpson, Professor E. A. Schäfer, Dr. G. A. Gibson, and Dr. W. Allan Jamieson. Lord Dunedin, in introducing Mr. Paget, explained the objects of the Research Defence Society and spoke in defence of scientific research. Mr. Paget then delivered a most interesting lecture, illustrated by lantern slides, on the work of Pasteur. He referred to Pasteur's early chemical discoveries, to his study of ferments, and to his study of disease in silkworms, begun in 1865, as a result of which he was able to show the causes of a condition so seriously affecting the silk industry in France. After the Franco-German war he began the study of diseases in man and animals, and discovered the principles of preventive inoculation. His work on anthrax had enormously diminished the mortality among sheep and cattle from this cause. In 1875 Pasteur demonstrated in the Paris hospitals the methods of aseptic surgery and proved to the French Academy of Medicine in 1878 the cause of puerperal fever. The lecturer also described the discovery by Pasteur of the preventive treatment of rabies. Among persons bitten by mad dogs and treated by the Pasteur method the mortality was 0·3 per cent. On the motion of Dr. Gibson a vote of thanks was given to the lecturer. The following office-bearers were elected:—President: the Duke of Montrose, K.T. Vice-Presidents: Lord Dunedin, P.C., LL.D., K.C.V.O., Sir William Turner, K.C.B., F.R.S., Sir John Batty Tuke, M.D., LL.D., and the Rev. A. Wallace Williamson, D.D. Honorary treasurer: Professor Harvey Littlejohn. Honorary secretaries: Dr. John D. Comrie and Dr. R. W. Johnstone. Professor Schäfer moved the adoption of the secretaries' and treasurer's reports, and Mr. J. M. Cotterill, Vice-President of the Royal College of Surgeons of Edinburgh, seconded.

Medical Graduation at Glasgow University.

The first of the autumn graduations in medicine took place at Glasgow University last week. Formerly only one final examination was held each year, but under a new arrangement there are now two—one in the spring and one in the autumn. Although the proceedings were of a formal character there was a large attendance in the Bute Hall, when Sir Donald MacAlister, K.C.B., presided. The degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on 48 graduands, of whom one received the degrees with honours and three with commendation. Three ladies graduated amongst the number.

The Payment of Interim Medical Officers.

Recently Kilsyth town council appointed a medical officer of health for the burgh for the period of one year. On intimation being made to the Local Government Board that body has written to the council pointing out that there is no authority under the Public Health or Burgh Police Acts for the temporary appointment, and it does not regard such appointment as legal or fulfilling the local authorities' statutory duties under these Acts. The Board also points out that the salary paid to an interim officer cannot rank as a claim against the medical officer grant.

King's Cross Hospital, Dundee.

A special meeting of the public health committee of the Dundee town council is to be held to deal with facts connected with accommodation for scarlet fever cases in Dundee. The committee has recommended the provision of temporary accommodation at King's Cross Hospital for 20 beds, at a cost of £2100, in view of the large number of scarlet fever and diphtheria patients. The number of cases is not greater than it has been, but the demand for admission is greater. The accommodation for fever cases is 112 beds, and there are in the hospital 154 cases. The resident medical officer at King's Cross and three of the nurses are on the sick list.

City Hospital Alterations, Aberdeen.

After extensive alterations and additions the Aberdeen City Hospital has had its new buildings formally opened. The cost of the extensions will be over £10,000, and instead of accommodating 127 patients as formerly, 200 can now be treated. The nurses' accommodation has also been considerably enlarged, and a large recreation-room added for their use. The new wards are built of granite with ashlar masonry, the size being similar to the present ones, an allowance of 2000 cubic feet being provided for each bed. They are heated by radiators fitted up in the window recesses and are ventilated by opening fanlights over the windows and gratings in the ceilings connected with ventilators fitted up in the roof. Altogether the additions are important and should much improve the usefulness of this institution for the treatment of infectious diseases.

Infantile Mortality in Aberdeen with regard to Pneumonia.

In his report to the Aberdeen town council for September Dr. Matthew Hay, the medical officer of health, states: "The deaths among infants under 1 year of age amounted to 49 during the month, as against 46 in the preceding month, and an average of 44 for the month of September in the preceding five years. The slight increase in the total number of deaths was much more than accounted for by a considerable addition to the deaths from pneumonia. These amounted to 11, as compared with an average of less than two in the corresponding month of the preceding five years. In the previous month there was only one death from this cause. There was also a slight increase in deaths from pneumonia at the ages of 1 to 5 years; but it was far short of the increase among infants. I have specially inquired into the circumstance of the deaths occurring among children under 1 year. The illness seems to have been largely of a zymotic type, as, except in two cases, its duration was under ten days, and in most of the cases only two to five days. In four cases there was no history of previous illness. In the remaining seven, the infants had been weakly—some of them since birth. The majority of the infants had been bottle fed. All the deaths occurred among children of the labouring and artisan classes, and therefore in small houses. The cases were scattered throughout the city, and had no discoverable connexion with each other, or with any previous known case of pneumonia among the family or among the neighbours or relatives. It may be remembered that there was a similar sudden rise of death from pneumonia at the end of last year, but it was accompanied by a corresponding increase in deaths from bronchitis. On this occasion no deaths from bronchitis have been registered as occurring among young children. The sporadic character of the pneumonia resembles closely that of cerebro-spinal fever as experienced in this city, and suggests that the cases of pneumonia may have been provoked by some little-understood weather conditions that may render weakly infants less resistant to pneumonia micro-organisms, which are now well-known to be practically at all times widely diffused in every community."

Oct. 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mr. Birrell and the Local Taxation Account.

ON Oct. 24th a deputation representative of several of the principal municipal and county authorities waited on the Chief Secretary to discuss the failure of the Local Taxation Account, to which reference was made in THE LANCET last week (p. 1248). Though Mr. Birrell was unable to promise immediate relief from the Imperial Exchequer, yet he gave the deputation some crumbs of comfort. He realised fully the gravity of the present situation, and he also admitted that the local authorities were in no way to blame. The increase in expenditure in the asylums had been unavoidable, and a further increase must be expected. This being the position, the whole scheme must be reconsidered, and to this reconsideration Mr. Birrell pledged himself. As regards the present position, he stated that it would be found that the deficit would not be so great as was believed at present. The ultimate solution of the problem has to be faced, and Mr. Birrell has invited the aid of Irish public opinion. It is to be decided whether lunacy is in future to be regarded as a local or as an imperial charge; if the former, in what way is help from imperial sources to be given, as a fixed grant per year or a fixed sum per lunatic? Whatever solution is put forward it should be one with a reasonable prospect of permanence, and not be dependent on an inelastic or bankrupt fund.

Fagan Memorial Fund.

The friends of the late Mr. P. J. Fagan, whose sudden death was recorded recently in these columns, have issued a circular appealing for subscriptions to a memorial fund. Still a young man in professional life, Mr. Fagan had been unable to do more than make a very frugal provision for his wife and children, though he left not a single debt. It is proposed to direct whatever subscriptions may be received towards the education of his children. Already a promising return is being made. Mr. R. F. Tobin, 60, St. Stephen's Green, Dublin, is one of the honorary treasurers.

Belfast Natural History and Philosophical Society.

The report presented to the annual meeting of the members of this society, held on Oct. 12th, showed that the negotiations between the society and the city council have been practically completed by which the specimens in the museum will be ultimately lent on permanent loan to the corporation, and will be located in the new municipal museum. Sir John Byers was elected, for the third year in succession, president of the society.

Oct. 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Professor Ehrlich's New Remedy, "606."

THE Academy of Medicine has devoted a portion of several of its meetings to discussions on Professor Ehrlich's new remedy "606," which has aroused such widespread interest throughout the medical profession. The subject was introduced on Oct. 4th by M. Hallopeau, who expressed the opinion that "606" did not fulfil the conditions of reliability and complete harmlessness necessary to justify the

eulogies which have been bestowed on it. He said that there have been already 14 deaths attributed to it, two of them in Paris, and it was possible that unrecorded cases of a fatal termination have occurred in private practice. Instances of blindness due to this cause have been met with, and it was beginning to be known that patients who had been treated for syphilis in this manner might have relapses of the disease. Its administration has also been followed by various disorders and derangements of the health, such as paralysis of the legs, paralysis of the bladder, albuminuria, diarrhœa, epileptiform attacks, and pneumonia. Hectine, which he had made known to the Academy some time ago, appeared to him to be far preferable; it was quite harmless, and none of the patients who had been treated with it at a sufficiently early stage has as yet suffered from relapses. M. Netter interposed with the remark that a man of Professor Ehrlich's high standing was worthy of credit. M. Balzer said that he agreed generally with the opinion expressed by M. Hallopeau. He regretted that no information was obtainable with respect to the deaths which had followed the administration of the new remedy, because if the facts had been disclosed practitioners might have been able to learn something from these enlightening incidents. He feared that medical men with no more than a superficial knowledge of the subject would yield to the entreaties of certain patients and resort too readily to powerful medicines the dangers of which had not been fully investigated. On Oct. 11th M. Netter read a letter which Professor Ehrlich had written to him in reply to the unfavourable comments made at the previous meeting. Professor Ehrlich said that he had not met with any instance of blindness consequent on the use of the new remedy. There had been one death of a patient who was a lunatic, and in reference to this he remarked that great caution was necessary in giving "606" to patients suffering from lesions of the nervous system. He concluded by saying that hectine, which was recommended by some French practitioners in preference to his new remedy, was patented in Germany, just as "606" was. On Oct. 18th M. Hallopeau, replying to Professor Ehrlich's letter, said that he could not understand why Professor Ehrlich refused to acknowledge the two cases of blindness which had followed the administration of "606" and had been reported in Germany. Professor Ehrlich considered that 12 deaths among patients who had received 8000 injections was a small mortality, but M. Hallopeau maintained that it was a high mortality as compared with hectine and some other antisyphilitic remedies which had never been followed by fatal results. To these 12 cases it was necessary to add four others which had occurred in Paris. M. Hallopeau gave an account of a case which supported his contention that a patient might recover completely from syphilis under the use of hectine; the individual in question was a man who, after treatment with hectine some months ago, was found to have contracted a second attack of syphilis. As syphilis usually confers such a degree of immunity that a second infection is decidedly uncommon, the inference is that the patient under the care of M. Hallopeau recovered completely from the disease and was practically in the condition of a person who had never suffered from it. M. Mouneyrat protested against a statement made by Professor Ehrlich to the effect that hectine was first made known in Germany and was patented there in 1906. An examination of the records, samples, and descriptions of manufacturing processes preserved in the German Patent Office showed that hectine was not one of the arsenical compounds patented at the time stated; indeed, it was probable that Professor Ehrlich had never had hectine in his possession. The new remedy "606" received more favourable consideration at a meeting of the Société Médicale des Hôpitaux held on Oct 14th, its therapeutic efficacy being highly commended by M. Jeanselme, M. Laignel-Lavastine, M. Touraine, M. Milian, and M. Netter. M. Jacquet said that it was advisable to be cautious in the use of antisyphilitic remedies, as some of them set up irritation which might cause tertiary syphilomata.

Precautions against Cholera.

As the epidemic of cholera in Naples has not yet subsided, measures of precaution continue to be taken on the French frontier. Every traveller coming from Italy, even although provided with a permit granted by the Italian sanitary authorities, is examined by French medical men in the railway station at Modane, and thereupon receives a permit which he must deliver to the police on arrival at his destination, at the same time informing them of the address at which he resides. Travellers coming direct from Naples are very strictly scrutinised. If they present even the slightest suspicious symptoms they are detained at Modane and isolated for the full period of incubation, which may be as long as seven days, after which, if there have been no further symptoms, they may continue their journey. As a general rule, there is no disinfection of travellers' luggage.

Oct. 25th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A Congress on the Care of Persons Suffering from Mental Defects.

AN International Congress on the care of persons suffering from mental defects was held recently in Berlin and was attended by a great many visitors from various European nations. The first subject that was considered was the connexion between civilisation and mental diseases, the discussion being opened by a paper read by Professor Tamburini of Pavia. He took the view that mental diseases had not increased in consequence of the progress of civilisation, but that their form had altered. The epidemic diseases formerly ascribed to mystic and even demoniacal influences, such as the flagellantism and the St. Vitus dance of the Middle Ages, had disappeared; hysteria, which was so frequent in modern times, prevailed in former centuries also, but was known by other names. Instead of the above mental diseases others had come into existence, caused by nervous overstrain, by the abuse of spirituous liquors, and by syphilis, but they might be counteracted to some extent by judicious precautions. Professor Rüdin of Munich said that epidemics of mental instability existed in the present day, but they did not now lead to the disorderly scenes which characterised their predecessors in the Middle Ages; he alluded to "Christian Science" and some other "comical" sects, as well as to the traumatic hysteria which in Germany had seized the working population since insurance against accidents had become compulsory. Civilised nations were undoubtedly showing symptoms of degeneration in consequence of modern endeavours to protect the weaklings and degenerates who formerly perished, and the offspring of these persons inherited their defects. Dr. Hellpach of Carlsruhe read a paper on psychopathological features in modern art and literature, illustrating his remarks by an analysis of modern novels and dramas from a psychiatric standpoint. Another subject of discussion concerned mental diseases in the army. Dr. Deknatel, of the Dutch army, said that the increase of insanity in armies was partly owing to overexertion, due to the fact that battles fought with modern weapons and in accordance with modern tactics made greater demands on the bodily and mental capacity of a soldier than could be borne by psychopathic recruits. All recruits ought to undergo psychiatric examination. Dr. Krause, of the German army, said that in Germany great stress was laid on precautionary measures, by which men who were either neuropathic or suspected to be so were as much as possible excluded from conscription, and the recruiting officers made careful inquiries as to the mental state of intending recruits. Nevertheless, a number of psychopathic recruits entered the army; continued misdemeanour, notwithstanding frequent punishment, was very often a sign of a psychopathic state, and such offenders should be observed by alienists. In several garrisons elementary lectures on mental diseases were now delivered to army officers by members of the Army Medical Corps, with a view to assisting the recognition of suspected cases. Dr. Krause stated that during the war in South-west Africa the incidence of insanity increased by 5 per cent. owing to the over-exertion of the men. Dr. Puetet, a French medical man, stated that the number of psychopathic persons was especially great among the volunteers. Professor Marie of Paris read a paper on the Importance of Wassermann's Reaction for the Diagnosis of Syphilitic Diseases of the Central Nervous System. He said that if the spinal fluid obtained by lumbar puncture gave a positive reaction syphilis was undoubtedly present and mere neurasthenia might be excluded. A discussion on Sleeping Sickness was opened by

Professor Ehrlich of Frankfort. He said that a certain likeness existed between general paralysis and sleeping sickness, because both diseases were influenced by the same pharmaceutical preparation. The trypanosoma was obviously of a different resistance against arsenic in different districts. In the colony of Togoland a "sterilisatio magna" was obtained without danger by doses of his preparation No. 606 which in East Africa were dangerous to life and at the same time failed to produce any beneficial effect on the disease. He had had good results by a combination of arsenic with trypan-red. In some cases treated in this way the patients had regained their health and remained quite well for the last eight months. Both general paralysis and sleeping sickness were very resistant when the microbe causing the disease had made its way into the spinal fluid, because the endothelium of the spinal meninges hindered chemical compounds of high molecular weight from entering. This difficulty must be overcome by the discovery of new preparations possessing similar therapeutic properties but of less molecular weight, and he hoped to be aided in this work by the alienists. Dr. F. W. Mott of London, in showing numerous microscopical preparations of the disease, said that sleeping sickness was only a clinical symptom of trypanosomatosis, caused by a perivascular infiltration of the cerebral vessels. He said that the trypanosoma was the same in every patient and that the disease was spread by a creature (a species of tick) which was everywhere the same. He proposed to term the disease human trypanosomatosis instead of sleeping sickness. Other papers read before the congress dealt with the importance of careful supervision of infants and young children, with a view to the prevention of idiocy and psychopathy, the establishment of sanatoriums for nervous patients of the less wealthy classes, and the teaching of forensic psychiatry. An exhibition was held in connexion with the congress and was very well attended.

Centenary of the University of Berlin.

The University of Berlin celebrated its centenary on Oct. 11th and 12th amid great manifestations of enthusiasm and a succession of impressive ceremonies. The principal event of the proceedings was an address delivered by the Emperor, who announced that a large sum (about £500,000) had been collected and given to him by private benefactors on the occasion of this centenary, and that with the approval of the Government he intended to employ this money for the erection of scientific institutions. In these institutions men of acknowledged eminence in their various fields of research would have an opportunity of devoting themselves exclusively to scientific work, unhindered by having to undertake the duties of university teachers and examiners. The institution for experimental therapy in Frankfort under Professor Ehrlich would serve as a model for the proposed institutions, from which medical science would unquestionably derive much advantage.

Oct. 24th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Memorials to Professor Nothnagel and Professor Gussenbauer.

Two memorial tablets, with very lifelike sculptured representations of Professor Nothnagel and Professor Karl Gussenbauer, were unveiled recently in the Aula of the University of Vienna. Professor Nothnagel, who died a couple of years ago, was characterised by great suavity of manner in his dealings with patients; he had a favourite saying to the effect that only a kind-hearted man could be a good physician, and this motto was inscribed on the tablet erected to his memory. Professor Gussenbauer was the successor of the famous surgeon Professor Billroth, whose intimate friend and pupil he had been, and he had a very brilliant career; though his manners were curt he won the esteem of everybody with whom he was brought in contact, and the fund for raising a tablet to his memory received very liberal support.

Disappearance of Cholera from Vienna.

During the four weeks which have elapsed since Sept. 23rd not a single case of cholera has been notified in the city and the cholera committee has therefore been dissolved. It was due to the combined efforts of the municipal and Government authorities that the threatening invasion was warded off. Altogether 7 cases with 3 deaths were observed in the city, and of these attacks all but one could be traced directly to the Hungarian steamers plying on the Danube between Vienna and riverside places in Hungary. It is now taken for granted that the river Danube is infected in the lower parts of its course. Amongst other precautions, a special look-out was kept on the portion of it within Vienna to prevent people from using the river water, which was not unlikely to be polluted by the infected Hungarian vessels moored in quarantine. The sale of grapes, 60 per cent. of which come to Vienna from Hungary, was also under very strict supervision. The energetic measures that were taken have caused much dissatisfaction amongst tradesmen, but the result upon the public health was most satisfactory. The extra expenditure under this head up to the present time amounts to £14,000.

Open Spaces in and around Vienna.

A favourite idea of the late Mayor of Vienna, for which future generations will owe him unbounded gratitude, is gradually coming into practical operation. He was the first to recognise that a broad ring of gardens, parks, and heaths round great Vienna was essential for the health of the population. He therefore always refused his consent to plans of building cottage suburbs around the city, but insisted on the laying out of parks. His projects were well received by the population, and when recently an extension of an existing park in the north of the city was opened it was at once called by his name, in disregard of its official designation. At present there is a girdle or zone of some 1400 yards breadth, consisting partly of cultivated land and partly of uncultivated areas, which completely encircles the city at a distance of some six miles from its centre. This area is not to be built upon, and beyond that circle only cottages with gardens in front and behind may be erected. There will also be an abundant supply of water for ornamental ponds and other purposes. At present there are eight large parks in Vienna with an area of more than a square mile, whilst smaller gardens are scattered all over the inner districts. The latest addition to the park measures a quarter of a mile on each side and consists chiefly of grass plots for the benefit of the children.

Professor Tandler's First Official Lecture.

Professor Tandler, the successor of the late Professor Zuckerkandl, opened the winter session of the Anatomical Institute with a lecture on the Correlation between Clinical Work and Anatomy. As is the custom here, a large number of professors witnessed the "maiden speech" of their new colleague. He pointed out that the practitioner must obtain help from the anatomist, and that it was an error to suppose that the anatomist begins where the practitioner leaves off, because a knowledge of anatomy was indispensable for nearly all modern operations and for many therapeutical procedures. Professor Tandler said that anatomy also helped the physiologist and the original investigator, both of whom contributed to the success of the practitioner at the bedside. A large number of students and medical men attended the lecture, and the presence of more than 80 female students showed that the professor is a pioneer in the movement for the admission of women to the study of medicine.

Phosphorescent Bacteria.

Although the connexion between gardening and bacteriology is not very apparent, some interesting bacteriological specimens were to be seen at a flower show and exhibition of garden produce recently held in Vienna. They consisted of a number of plates with cultures of Pseudomonas lucifera and Bacterium phosphoreum, prepared by Dr. Molisch, director of the Physiological Institute, who has devoted special attention to the study of phosphorescent bacteria. The first-named micro-organism was discovered on shellfish, and is now cultivated in gelatine containing 1 per cent. of peptone. Cultures of this bacterium emit a bluish-green luminosity capable of lighting up a small room to such an extent that large print can be read. This is the only genus of bacterium which gives off rays visible in the spectrum. Dr. Molisch has found that meat which has been kept for some time, slices of boiled eggs, and potatoes are the best media for cultures of the Bacterium phosphoreum, which can be made to intensify its brilliancy

by variation of the media. The light is not accompanied by heat rays capable of detection by any known method. These self-luminous cultures have aroused much interest and form an attraction for many medical men.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

SINCE the first week in August there has been a continuous increase in mortality from plague, the total reported deaths for the week ending Sept. 10th being 2057, as compared with a total of 610 four weeks back. The latest provincial figures are: Bombay Presidency, 625; the Central Provinces, 402; and the United Provinces, 135; while Central India returns 256 deaths. The worst affected district in British India is the Buldana district in Berar, which has suffered a mortality of 162. Baroda State accounts for just under one-third of the deaths reported from the Bombay Presidency.

Proposed Medical College for the Central Provinces.

Three proposals have been put forward regarding the form of a memorial to his late Majesty King Edward for the Central Provinces, viz.: (1) King Edward Sanatorium for consumptives; (2) King Edward Medical School; and (3) King Edward Scholarship. Rai Sahib Mathura Prasad, pleader of the Central Provinces, favours the second of these schemes, and has prepared an interesting note on the subject in the course of which he says: "Every province in India has been provided with at least one medical college to meet local requirements and to remove local wants. There is certainly no reason why our province, with its teeming population and the rapid advance it is making in the march of civilisation and progress, should be thrown in the cold shade of neglect. How will it be possible for the Central Provinces without a proper training institution to stand up in competition with other provinces when Lord Morley's scheme of constituting a medical service consisting of Indian medical practitioners only is put into execution? Moreover, evidence will not be wanting to prove that candidates of our province who had the courage and means of going to other provinces have been denied admission into the colleges of those provinces on the simple ground that those institutions were intended more for local boys than for foreigners. The heavy expenses and the risk which the prolonged residence in distant provinces involves prevent many aspirant youths from joining the profession, which relieves human sufferings. The total absence of any medical college in our province for the proper training of men in this noble profession is responsible for the paucity of qualified candidates to take charge of dispensaries and hospitals. Instances will be at once forthcoming to show that a large number of dispensaries could not be opened in this province for want of qualified men in spite of the funds made available for their maintenance and support. There is thus abundant proof that the medical service and the profession are undermanned with us." He quotes figures showing that only one medical man is available for every 31,256 persons, and only one dispensary for every 60,442 persons. The existing number of hospitals and dispensaries, he says, are so situated as to allow daily only 9633 persons out of the total population of the province to get medical relief. The wholesale extension of medical help into the interior of the provinces amongst a mass of village population which is at present at the entire mercy of illiterate, ill-educated, and untrained persons, will speedily put a stop to the heavy mortality of men, women, and children who are dying in large numbers from sheer want of proper administration of medicine and medical assistance.

Instruction in Malarial Fever Prophylaxis at Amritsar.

The anopheline mosquito is not a particularly large insect, and it is remarkable to reflect how much laborious research its little body and malignant activities can give rise to. Six hard weeks of study were spent at the beginning of the hot weather of this year by the malaria class held in Amritsar and its instructors in verifying most of what is known about this ubiquitous form of life and its habits, and during the time so much was accomplished that is by no means easy even to give a *résumé* of the work done in a short space. In order to show the thorough nature of the researches undertaken it may be observed that the first fortnight of the course was devoted to the examination of the mosquito itself, both of the anopheles and culex varieties, and of either sex of each. The general appearances and particular features, not only of the full-grown insects, but also of the larvæ and nymphæ, were carefully noted, and the methods were learned of searching for, collecting, mounting, and identifying larvæ and of breeding out and collecting adult mosquitoes, as well as the chief anatomical features of the insects. A study of scale structure was entered into to facilitate the identification of anopheline genera, while the species were distinguished by means of synoptic tables. The third week was devoted to "blood work"—the study, that is, of methods of obtaining blood specimens in villages exemplified by the collection of films in Amritsar and the neighbouring villages. Next came the dissection of the mosquito and the study of its anatomy and various stages of development in detail, which occupied the fourth week, during which the systematic collection of adult anopheles in villages and their internal examination was carried out by members of the class, while opportunity was also taken to study the ova of as many species of anopheles as possible. Malarial survey-work in field and laboratory, map entries, critical examination of mortality statistics of affected areas, and a close study of social and economic conditions occupied a further fortnight, and after the completion of the work in Amritsar city a malario-physiographical survey was made of a neighbouring rural tract, affording much detailed discovery useful for registration. A few more days were devoted to revision and to methods connected with the clinical study of malaria, and throughout its period of study the class was privileged to examine special collections sent from Burma, Bengal, Madras, Bombay, the Punjab, and other regions through the kindness of various officers, as well as a large collection of selected slides showing parasites. If there are medical officers in India ignorant of the true inwardness of malaria and of its conveyers these were evidently not at Amritsar during March and April of this year. There can be no doubt that India will have reason for gratitude in plenty to those whose attendance at the thorough-going class in question will have invested them with a complete and detailed knowledge of one of India's most formidable enemies.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Child Mortality.

IN September of last year I noted the results of questions put to a thousand Chinese mothers who came to the British Charitable Hospital out-patient clinique. I found it impracticable to get the ages at which the children died, but this was to some extent regulated by leaving out elderly women whose families had time to grow up, thus eliminating adults. The mortality of the first thousand was somewhat heavier than that of the second, but, as the figures will show, there is an appallingly high death-rate such as would not at the present time be tolerated in any European country.

1000 mothers each year.					1909		1910
Total number of children born...					4723	.....	3555
,,	,,	,,	,,	alive...	2342	.....	1899
,,	,,	,,	,,	dead...	2381	.....	1656
,,	,,	,,	boys	alive...	1301	.....	1023
,,	,,	,,	,,	dead...	1253	.....	869
,,	,,	,,	girls	alive...	1041	.....	876
,,	,,	,,	,,	dead...	1128	.....	787

In Hong-Kong, where there is birth registration, the infant mortality last year was *873 per 1000* among Chinese. It will be seen from the above table that the male births are in excess of those of the females. In European countries the female births steadily exceed those of the males and in England certainly there has been this female preponderance for a number of years. In some notes made by Dr. E. M. Merrins of Wuchang in Mid-China these results are corroborated. He found that in a series of anthropometrical

measurements on 1920 young Chinese the birth-rate was 64 per cent. for boys and 36 per cent. for girls. He also found the death-rate among the girls to be 7 per cent. higher than that of the boys. The average family all over the Empire consists, including parents, of 6·5 persons, but deaths reduce this figure to 4·5. It is interesting to compare this with the average of English and American homes, as no less a statesman than ex-President Roosevelt thinks that the Chinese at the present day are not increasing relatively as fast as the Anglo-Saxons, who will consequently soon be within measurable distance of equality with them in point of numbers, and therefore the industrial and commercial competition of the Chinese need not be feared abroad. Figures such as I have given should emphasise the need of national and provincial bureaux of vital statistics. There is now an intense national feeling among the Chinese to come into line with other civilised nations, but there still remain the utmost apathy and indifference to human life and public health.

Prohibition of the Importation of Cocaine.

The Imperial Maritime Customs have issued a notification to the effect that the manufacture in China by Chinese and foreigners of cocaine and of syringes, needles, and such-like instruments for its use is absolutely prohibited, and the importation of the same into China is likewise prohibited except in the case of duly qualified foreign medical practitioners and foreign chemists. The latter must conform to certain regulations which state that "duly qualified medical practitioners desiring to import cocaine or instruments for its use must sign a bond before their Consul stating the quantities to be imported and their value. Foreign chemists must adhere to the same conditions." Duty will be levied at the rate of 5 per cent. *ad valorem*.

The Cocaine Habit.

Not long ago a memorial was presented to the Throne by a provincial Viceroy, in which the attention of the Imperial Government was called to the fact that since laws had been established restricting the sale and use of opium the Chinese in no small numbers were finding consolation in cocaine. While in morphinomania the practice may cover an indefinite period without marked effect on the nervous system, the results of taking cocaine habitually are distinctly disastrous. Within five or six months a man may become a mental degenerate, not infrequently developing temporary insanity. An outbreak of the habit occurred last spring among marines in the American Legation Guard at Peking, and six privates were found suffering from it. The surgeon in charge, Dr. W. D. Owens of the United States Navy, in a series of 10 cases detected as an important sign, which has not hitherto been included in the usual classical description, epistaxis and ulceration of the nasal mucous membrane. In one patient who sought treatment for nasal catarrh, in addition to the ulcers, examination elicited necrosis of the nasal chambers. The usual mode of taking cocaine among Chinese and foreigners is by snuffing it or by cocaine-containing catarrh snuffs. Two patients who had been under treatment for epistaxis subsequently gave decided signs of being cocaine habitués. The epistaxis is accounted for by the severe congestion produced by cocaine upon the Schneiderian membrane and the increased blood pressure incident to its use. The impurities in many of the preparations used also have an ulcerative effect upon the sensitive membrane. An opium smoker suffering from the mental depression which ensues on eschewing the opium habit finds in cocaine a feeling of pleasure, relief from worries, a sense of elation, new life, and increased mental vigour. Hypodermic syringes are not much used in China, the method preferred being a quill, by means of which a dose can be passed well into the nasal cavity. It is to be hoped that the new regulations will be sufficient to prevent the easy purchase of cocaine, though in the absence of any coast preventive service there is no country in the world into which it is less difficult to smuggle goods or drugs of any description than China.

Sept. 26th.

A DEVONSHIRE CENTENARIAN.—Mrs. Caroline Sutherland of Plympton, who celebrated the hundredth anniversary of her birthday on Oct. 19th, 1909, died on Oct. 9th last.

Obituary.

DAVID HALKET STIRLING, M.D. EDIN.

THE death of Dr. D. H. Stirling, which occurred on Oct. 14th, as briefly mentioned last week by one of our Scottish correspondents, has been much regretted in Perth, his native city, where he spent a long and useful life in the service of all classes of his fellow citizens, and where, although he had reached the age of 81 and had retired from the more active duties of his profession, he remained a notable personality. His energy was remarkable, and throughout his career he was one of those able practitioners who cannot confine their interest to the technique of medicine and surgery His sense of duty led him to undertake social work and to labour continuously in many fields of usefulness where there seemed opportunity for the improvement of the people and the relief of human suffering. Therefore his death has left a great gap among his fellow-citizens at large, while "from the intimate personal point of view," writes one of his friends, "in the course of all the changes and experiences of a generation, never once did he fail in ready aid, never once did he turn aside from the way of kindness."

Dr. Stirling was born in Perth and was educated in the academy of his native town. Thence he proceeded to Edinburgh, where he graduated as M.D. and became a Licentiate of the Royal College of Surgeons in 1853. Thereafter he pursued his studies in Paris and Vienna, but he held that his education could never be completed until he was no longer able to appreciate the advances which are daily being made in his beloved profession. That was characteristic of his agile and untiring brain, and in the end he had the help of his daughter in pursuing his researches. After working for a time at Gray's Hospital and the District Asylum of Elgin Dr. Stirling returned to Perth and entered upon the work of general practice. He at first had doubts if he were right in continuing in a county town of moderate size, but happily he was persuaded and did not remove to a larger sphere. He found his place of trusted usefulness, as many other distinguished men have, in a centre where the advantages of a great population or a university are absent.

From 1868 until 1884 Dr. Stirling served on the staff of the Royal Infirmary, Perth, and there instituted a reorganisation of the nursing department as one of the improvements which marked his term of office. When he was appointed consulting medical officer the directors expressed their appreciation of the value of his work, and retained the advantages of his experience in conferring with him from time to time. It had become evident to Dr. Stirling that the Royal Infirmary could not undertake the care of the sick and afflicted of all kinds, and he conceived the idea of instituting the Hillside Homes for Treatment of Chronic Ailments to make good this defect. This institution was begun in a modest way; but with indefatigable zeal Dr. Stirling gathered round him influential supporters, and impressed them with new ideals as experience led him to develop the Homes. The original principle of limiting the sphere of its operations to incurable patients was found to be too partial. From year to year, therefore, the operations of the Homes have been enlarged, and all kinds of chronic patients have been admitted and suitably treated, in the various houses of the institution, the number for last year having been 246. The sanatorium branch of the Hillside Homes has been provided for phthisical cases in the early stages, and much good work has been done under Dr. Stirling's fostering care. The large sum of money which he collected during the last 33 years has been applied to the building and maintenance and to an endowment fund which gives stability to the whole institution.

Dr. Stirling's deep religious habit of mind was shown early in his career, for he was the founder of the City Mission, and continued to act as secretary till the end of his life. The poor people succoured by the mission were mindful of what he had done for them, and only a few months ago he was presented with an illuminated address bearing the touching words that "many would have liked to have shared in the testimonial, but only the poor were allowed to subscribe, and more than 400 gladly gave their mites." His medical colleagues also presented Dr. Stirling with his portrait on the occasion of his professional jubilee. He was thus fortunate

in the recognition of his worth and the encouragement afforded to him by his many friends.

Dr. Stirling married the sister of the late Dr. Lauder Lindsay. She predeceased him, as also did his son, Mr. James Lindsay Stirling, of the India Civil Service. Dr. Robert Stirling, his elder son, is a medical practitioner in Perth. It should be added that Dr. Stirling travelled widely and had a great admiration and personal knowledge of foreign missions. He wrote on leprosy in Norway, on medico-legal investigations, and on pulmonary tuberculosis.

Medical News.

THE SOCIETY OF APOTHECARIES OF LONDON.—As we announced last week, the Master and Wardens of the Society of Apothecaries attended Divine service on Oct. 18th, St. Luke's Day, at St. Anne's by the Wardrobe, and dined together in the evening at their Hall, the occasion being the induction of the new Master, Mr. A. T. Norton. The guests were the Deans of the Medical Schools and the Court of Examiners. After the loyal toasts, "The Society of Apothecaries" was proposed by Mr. E. Parker Young and responded to by the Master, who took advantage of the occasion to discuss the subject of the removal of names from the Register for "infamous conduct" and the objects of the private Parliamentary Bill recently promoted by the Society. In reference to the former, he said all the men whose names were removed from the Register deserved their punishment, but there were some pitiable cases of hard-working men whose names were removed for allowing an unqualified man to see patients. Such painful cases should be prevented; the circumstances leading up to the breaking of that law could be avoided, and as there were present many general practitioners in large practice and many lecturers and teachers on the staff of every large hospital and medical school, it behoved every one to bring to the notice of students about to enter into general practice that they should never have in their establishment any sort of assistant unqualified, and yet in his own estimation capable of visiting and prescribing for patients, for should they do so they would be sure to make use of his services at a pinch and thus render themselves liable to have their names removed from the Register. The Society of Apothecaries held an examination for dispensary assistants of both sexes, a searching examination on the knowledge of drugs, poisons, doses, incompatibles, method of dispensing, &c., qualifying candidates to assist medical men, not to act as pharmaceutists or to keep shops. On the subject of the private Bill recently promoted by the Society, the Master said the object of the Bill was to place the Society on a par with other examining bodies in the granting of diplomas in public health, dentistry, &c. The Act contained words to the effect that examining bodies holding examinations in medicine and surgery might grant diplomas in those subjects registrable by the General Medical Council. Other examining bodies had taken care that they should be specially mentioned in an explanatory clause as colleges, faculties, and universities, &c., and as the Society of Apothecaries did not come under one of these titles counsel had given the opinion that the General Medical Council could not register such diplomas granted by the Society. There could be no question that the Act was never intended to exclude the Society of Apothecaries, but he was given to understand that the private Bill was not proceeded with not on account of objectors, but on account of the fact that it would over-ride the Act of Parliament. The examining bodies, and indeed the whole profession, were in a state of unrest with regard to the Medical Acts, and these would certainly undergo revision as soon as a Government of either political creed could give time to their consideration, and the Society must see that it stood in by name with the other examining bodies. The toast of "The Deans of the Schools and the Court of Examiners" was proposed by the Senior Warden, and responded to by Sir John Broadbent for the Deans, and by Dr. J. W. Carr for the Court of Examiners. "The Chaplain and Preacher of the day," proposed by the Junior Warden, was responded to by the Chaplain. Between the toasts the company were agreeably entertained by well-rendered music.——At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—N. S. Adler (Sections I. and II.), Berlin; D. E. S. Davies (Sections I. and II.), King's College Hospital; E. B. Keen (Section I.), Charing Cross Hospital; J. K. Nariman (Section II.), Bombay and St. Mary's Hospital; and H. S. Tumber (Section II.), Sheffield.

Medicine.—G. A. Crowe, London and St. Thomas's Hospitals; E. D. Richardson (Section II.), St. Mary's Hospital; and C. J. Thompson (Section II.), Birmingham.

Forensic Medicine.—J. G. Lewis, Durham; and G. S. Richardson, Leeds.

Midwifery.—J. E. S. Sheppard-Jones, St. Thomas's Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—J. K. Nariman, E. D. Richardson, and H. S. Tumber.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. R. Jolly, *privat-docent* of Gynæcology, has been granted the title of Professor.—*Bologna:* Dr. Giuseppe Silvio Torri has been recognised as *privat-docent* of Medical Pathology.—*Budapest:* Dr. Felix Szontágh, *privat-docent* of Pædiatry, has been granted the title of Extraordinary Professor.—*Genoa:* Dr. Livierato, Extraordinary Professor of Internal Pathology, has been promoted to be Ordinary Professor.—*Göttingen:* Dr. Creite has been appointed *Oberarzt* of the Surgical Clinic.—*Halle:* The Charge of the University Otological Clinic being vacant through the death of Professor Schwartz, has been given during the vacancy of the professorial chair to Dr. Jsemer, who has been granted the title of Professor.—*Heidelberg:* Dr. Kurt Laubenheimer of Giessen has been recognised as *privat-docent* of Hygiene.—*Kharkoff:* Dr. Svietukhin, *privat-docent*, has been appointed Extraordinary Professor of Medical Diagnosis.—*Lausanne:* Dr. A. Eperon has been promoted to the chair of Ophthalmology in succession to the late Dr. Marc Dufour.—*Naples:* Dr. Fredrico Mazonne has been recognised as *privat-docent* of Surgical Anatomy and Operations; Dr. Raffaele Chiarolanza as *privat-docent* of External Pathology; and Dr. Luigi Guglianetti as *privat-docent* of Ophthalmology.—*Prague (German University):* Dr. Anton Ghon of Vienna has been appointed Professor of Pathological Anatomy.—*Vienna:* Dr. Heinrich Reichel has been recognised as *privat-docent* of Hygiene; and Dr. Michael Eisler, Edler von Terramare, as *privat-docent* of General and Experimental Pathology.

THE MURDER OF MAJOR JAMES HAMILTON NICHOLAS, R.A.M.C. (RETIRED).—At the Cornwall Assizes held at Bodmin on Oct. 21st, before Mr. Justice Bankes, James H. Nicholas, aged 26 years, was indicted for the murder of his father, James Hamilton Nicholas, L.R.C.P. Irel., L.R.C.S. Edin., Major R.A.M.C. (retired), at Maker, on August 16th last. Mr. S. Wolferstan, the medical officer at the Plymouth Prison, stated that the accused was of unsound mind. The jury found that he was also insane when he committed the crime, and his lordship consequently ordered the prisoner to be kept in custody during His Majesty's pleasure.

RUSSIAN DEMAND FOR "606."—The Moscow town government has ordered for its pharmacy a quantity of the Ehrlich "606" preparation and will, it is stated, dispense it regularly from the month of November. A message to the *Novoe Vremya* adds that the factory which makes the preparation is giving Russia a preference over all other countries, excepting Germany. Russia is calling for 100,000 phials for distribution amongst various municipal institutions in the capitals and provinces, 12,000 being the estimate for Moscow hospitals alone. An account appears in the same paper of observations made on two lepers at the Yamburg leper station with Professor Ehrlich's "606." Having consulted with Professor Ehrlich through the post, Dr. G. L. Yudelevitch determined to try the new method on some of the leper patients. Most of them manifested an indisposition to undergo the test. Two young men of about 20 years of age, whose leprosy was of about ten years' standing and whose internal organs were quite healthy, were consenting parties, and were selected. Both were severe sufferers from photophobia, and one of them had a large ulcer on the leg. Both were warned that the experience might turn out very unpleasant, and that particularly they might find any unpleasant effects mostly in the eyes. They suffered very little pain from the injection, and on the day after it was made, to the surprise of the medical attendant, their fear of the light had gone and their temperature had fallen by about a degree. The reduced

temperature remained permanent, as did the improvement in the eyes; whilst the ulcer on the leg of one of them shows signs of improvement—in fact, shows signs of cicatrisation. The results have been such as to encourage observations in the Yamburg Colony on a larger scale.

THE ALEXANDRA NURSES' HOME, DEVONPORT.—On Oct. 15th Mrs. F. B. Mildmay formally opened the new Alexandra Nurses' Home at Devonport.

PRESENTATION.—The committee which was appointed to arrange for the reception given by the corporation to the British Medical Association in the Guildhall in July has presented its chairman, Alderman Sir Thomas Crosby, with a silver centre-piece as a souvenir of the occasion.

DEVON MEMORIAL TO THE LATE KING.—At a public meeting recently held in Exeter under the presidency of the Lord Lieutenant of Devon, it was decided to invite subscriptions for a "King Edward VII. Memorial Fund." It was also determined that the fund should be administered by the council of the "Devon Queen Victoria Commemoration Fund," which was instructed to allocate the fund to district nursing associations within the county that are affiliated with Queen Victoria's Jubilee Institute for Nurses, and also to utilise some of the subscriptions in combating tuberculosis in Devon. Up to the present the sum of £1272 has been received.

BLOEMFONTEIN AS A HEALTH RESORT.—The weekly edition of the *Cape Times* of Sept. 21st contains an illustrated account of Bloemfontein from the point of view of a health resort. The town, which has a complete modern water-borne sewerage system and a plentiful supply of good water, certainly appears to be a desirable place to visit, the climate being good, the railway facilities convenient, and its natural features attractive. The statement of the writer of the article that "it is quite a frequent occurrence for periods of a month and longer to elapse without there being a single notification of infectious disease" is also a very good testimonial. It is interesting to note that the name Bloemfontein has no connexion with "flowery fountain," the town having got its name from a certain pioneer, Bloem, who made his temporary dwelling by the fountain which still exists near the Victoria Park.

MANCHESTER ROYAL INFIRMARY OLD RESIDENTS' CLUB.—A successful dinner of this recently formed club was held on Oct. 15th at the Midland Hotel, Manchester. The club arose out of a dinner held two years ago shortly before the closing of the old infirmary, for it was then felt that a periodical gathering should take place at which those resident at the same time should have an opportunity of seeing each other. Mr. F. A. Southam was President, and Dr. W. O. Jones (Bowdon), Dr. T. M. Johnson (Pendleton), Mr. Andrew Boutflower, and Dr. H. O. Pilkington acted as vice-presidents; 157 members were present. Dr. Pilkington proposed the toast of the "Manchester Royal Infirmary," and Dr. Arnold Jones that of "The President." Speeches were few and short in order to give men the opportunity of talking over old times. A strong feeling was expressed that meetings should be held every third year.

THE RÖNTGEN SOCIETY.—The Röntgen Society, which was founded in 1897, and is the parent society of the Electro-Therapeutic Section of the Royal Society of Medicine, will begin its fourteenth session on Nov. 3rd, at 20, Hanover-square, W. The lecture by Professor Rutherford will be listened to with much advantage. Professor Rutherford has the unique advantage of possessing more radium than anyone else in the British Isles. The price of radium at the present time is about £224,000 per ounce, and the price of small quantities is difficult to estimate, but the Röntgen Society possesses three carefully prepared standards by which the value of unknown quantities of radium can be compared and their value estimated. Professor Soddy of Glasgow, whose work is well known in connexion with radium and in conjunction with Sir William Ramsay and Sir James Dewar's work on helium, will also lecture. From Amsterdam will come a great physicist in the person of Professor Salomonson, who will unfold some original work on the mysteries of the working of an induction coil by which X rays are produced; and Professor Barkla of King's College will describe the results of some original work on X rays. Mr. J. Hall-Edwards, who has now freed himself from his former suffering caused by X rays, has also promised to take part. The lectures will be published in the Journal of the Röntgen Society. Invitations and further information can be had from the honorary secretary, Dr. A. Howard Pirie, 7, Harley-street, London, W.

DONATIONS AND BEQUESTS.—Under the will of the late Captain H. B. Murray the West London Hospital will receive £1050 for the endowment of a bed, St. Thomas's Hospital and St. George's Hospital will each receive £1000 for a similar purpose, and King's College Hospital and St. Mary's Hospital will also receive £1000 each. To the Hospital for Children, Great Ormond-street, and the Victoria Hospital for Children, Queen's-road, Chelsea, for the endowment of cots, the testator bequeathed £500 each, and £500 each to the Royal Dental Hospital and the London Fever Hospital, Liverpool-road, N., for general purposes, and £100 to the Cancer Hospital, Fulham-road, for general purposes.—Among other large bequests the late Mrs. Sarah Hancock has left £1000 to the Royal Hospital for Incurables at Putney.—As a result of a carnival held at Exmouth (Devon) the sum of £133 has been divided amongst several Exeter and Exmouth medical charities.—As a result of a horticultural show recently held at Alveston (Gloucestershire) the sum of £118 has been handed to the Bristol medical charities.

SOCIETY OF INFANT CONSULTATIONS.—A meeting was held on Oct. 19th at the Marylebone General Dispensary, under the chairmanship of Mr. A. Wynter Blyth, to inaugurate the formation of this society. Dr. Eric Pritchard, chairman of the executive committee, pointed out the value of infant consultations and the necessity of consolidating the many isolated efforts now being made to deal with the subject of infant mortality. Dr. J. F. J. Sykes stated that he was forming a society to deal with infant mortality in St. Pancras, and that he hoped their efforts would not overlap. On the proposal of the chairman it was decided that the society should be founded, having for its objects the bringing together of those interested in the work of infant consultations, and the recording of their experiences by holding meetings, reading papers, and collecting literature. It was agreed that the annual subscription should be 2*s.* 6*d.*, and all who wish for further information should address either of the honorary secretaries, Dr. Ronald Carter, 11, Leonard-place, Kensington, W., or Dr. Janet Lane-Claypon, 69, Prince of Wales's Mansions, Battersea Park, S.W.

BOOKS, ETC., RECEIVED.

AMERICAN LARYNGOLOGICAL ASSOCIATION (Secretary: Dr. James E. Newcomb, 118, West 69th Street, New York City).

Transactions of the Thirty-second Annual Meeting of the American Laryngological Association held at Washington, D.C., May 3rd, 4th, and 5th, 1910. Price not stated.

FREEMAN.—On Oct. 18th, at Devonshire-place, W., the wife of Dr. John Freeman, of a son.

JEANS.—On Oct. 22nd, at 30, Rodney-street, Liverpool, the wife of Frank Jeans, M.A., M.B. Cantab., F.R.C.S. Eng., of a daughter.

SINGTON.—On Oct. 25th, at Cleveland-gardens, Hyde Park, to Dr. and Mrs. Harold S. Sington, a son.

SPRAWSON.—On Oct. 22nd, at Manor House, Milton, Wells, Somerset, the wife of Captain C. A. Sprawson, M.D. Lond., I.M.S., of a son.

MARRIAGES.

BROWNE—PETER.—On Oct. 19th, in Looe Parish Church, Selina Ethel, second daughter of R. A. Peter, J.P., of Klymiarven, Looe, to Major Frank Dennis Browne, I.M.S.

FOLLIT—HURST-HODGSON.—On Oct. 22nd, at St. Pancras Church, London, Harry Harold Baily Follit, M.A. Cantab., M.R.C.S., D.P.H., to Hermione Millicent Burney, eldest daughter of Thomas Emanuel Hurst-Hodgson, of St. Mary's Abbey, Bedford.

HOW—SUTTHERY.—On Oct. 20th, at St. George's Church, Weald, Sevenoaks, by the Rev. Harold Sutthery, brother of the bride, and the Rev. W. Minto Roberts, Vicar of the parish, F. F. Lawrence How, son of Frederick How, Esq., of The Forelands, Chesham, to Ethel Catharine (Dick), daughter of the late Rev. William Sutthery, Rector of Clifton Reynes, Bucks, and Mrs. Sutthery, Chesham.

DEATHS.

CÆSAR.—On Oct. 17th, the result of an accident, Richard Thompson Cæsar, M.R.C.S., L.S.A., of Bearsted, Kent, aged 72 years.

MRS. KAYLER regrets that she is unable to reply personally to the many kind letters of sympathy she has received from the friends and colleagues of her deceased father, Sydney Ringer. She trusts they will accept this acknowledgment of her sincere thanks.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PHYSICIANS AND CITIES.

To the Editor of THE LANCET.

SIR,—Your note last week under the above heading was very suggestive of the growing prevalence of sanitary doctrines.

The view taken of the medical man's position in the State has varied, naturally enough, at different periods of the world's history. In Homer's time the army surgeon was regarded as worth a large number of other men on account of his skill—

> ἰητρὸς γὰρ ἀνὴρ πολλῶν ἀντάξιος ἄλλων
> ἰοὺς τ' ἐκτάμνειν ἐπί τ' ἤπια φάρμακα πάσσειν.
>
> Il. xi. 514.

"For a leech is worth many other men, to cut out arrows and to spread soothing applications (on the wound)."

Plato in his Republic declares that the ideal physician should be one who had experienced all kinds of diseases in his own body. But he was not to treat every kind of disease, only epidemics and wounds. Patients who were ill from their own fault—i.e., from excess in any shape or form—were to be left to die, being no good to themselves or to the State (The Republic, Bk. III., 407 et seq.). Modern ideas differ from this, and it is not often nowadays that a physician is also an architect, at least not with dead stones. But the glory of the modern profession of medicine is that it deals with the living stones of the great temple of humanity. Drainage, sanitation, and prevention of disease are the edifices which the modern medical man raises in our modern cities. It is difficult to realise that only 50 years ago much of the space between St. Bartholomew's Hospital and St. Paul's was occupied by cellar slaughter-houses, into which wretched sheep were pitched, often to lie awaiting slaughter with broken legs, while blood and offal lay about in the gutters. From these and similar horrors with their train of disease and death modern medicine has delivered us. It is a significant fact that to-day anyone passing in front of the National Gallery sees the excavation for one of the main sewers of London in the roadway. The æsthetics of healthy bodies are no less important than the æsthetics of beautiful buildings or pictures, although a healthy community has a tendency to demand beauty both in its recreations and its buildings.

The Town Planning Conference, to which you have alluded but briefly, shows that this feeling is now abroad.

I am, Sir, yours faithfully,

A BART'S MAN.

BURIAL GROUNDS AND PUBLIC HEALTH.

A PROPOSAL was made recently by the Eastbourne burial board with the object of acquiring additional land for the enlargement of the principal borough cemetery at Ocklynge, but on the grounds that the public health might be endangered if such an enlargement were made the proposal has been abandoned. Application was made by the board to the Duke of Devonshire, the owner of the land adjoining the cemetery, but the views of his grace were foreshadowed by the figure he placed on the land. Seventeen years ago the late Duke sold 10 acres for £7000, or £700 an acre. The present Duke has asked £12,500 for 7½ acres, or about £1700 per acre. A vestry meeting discussed the offer, but decided before proceeding further to consult Dr. W. G. Willoughby, medical officer of health, and that gentleman's report has resulted in the Duke of Devonshire withdrawing the offer he made. Dr. Willoughby's report was as follows: "From a sanitary point of view the chief nuisances liable to be caused by the cemetery are the pollution of water-supplies and the emission of obnoxious gases from the ground. As there are no domestic water-supplies in the vicinity to be considered, the former of these two items hardly comes into consideration, the Eastbourne water-supply being taken from sources some miles distant. The matter of the emission of gases is, however, more important. The opinion of the official medical advisers of the English Government, according to the memorandum of 1838, was that a distance of 200 yards is sufficient to prevent any injury to health as regards noxious matter transmitted through the air from a well-kept cemetery. The desirability of the enlargement of the Ocklynge cemetery, from a sanitary point of view, depends, therefore, on its liability to be sooner or later closely surrounded by houses, and if so, the fewer persons buried there the better. Judging from past experience, there being apparently no provision to prevent houses from being built close up to a cemetery, houses will probably be built within what might be called the 'danger zone' of the Ocklynge cemetery, whether enlarged or not. The more the interments, the greater the possible risk; the number of corpses in proportion to space being also an important consideration." It would have been difficult to see how after such a report as this the burial board could have come to any other conclusion than to abandon the proposed extension. Moreover, the question is not a

very pressing one. Consecrated land will be available at Ocklynge until about the year 1925, and unconsecrated until about the year 1916, at which latter date burials of that class will take place at Langney. Here there are 16½ acres of land—sufficient burying-space for another 30 or 40 years.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Nov. 7th-12th (Cape Town).—Twelfth South African Medical Congress (1910).

In 1911:—

May-October (Dresden).—International Hygiene Exhibition.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
Sept. 11th-16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 18th-23rd (Sydney).—Australasian Medical Congress.
,, 24th-30th (Rome).—International Congress on Tuberculosis.
,, 25th-29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.

In 1912:—

September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
September (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—

(London).—Seventeenth International Congress of Medicine.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham), at the London Hospital Medical College, E.: at 8.30 P.M.

Dr. Leonard Hill: The Influence of the Movement of the Air on Human Beings.
Dr. Martin Flack: Action of the Serio-auricular Node.
Mr. F. W. Twort: Cultivation of Bacillus Lepræ and the Bacillus of Johne's Disease.
Dr. W. Bulloch and Mr. P. Fildes: A Study of Tubercle Bacilli Isolated from Cases of Pulmonary Tuberculosis in Man.
Dr. James McIntosh: The Influence of dioxydiamidoarsenobenzol on Spirochæte Infections.
Dr. W. Bulloch: The Pedigree of a Great Family of Hæmophiliacs.
Dr. H. M. Turnbull: Pathological Anatomical Preparations.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—G. F. Blacker, J. H. Targett), at 11, Chandos-street, W.: at 8 P.M.

Specimens:
Lieut.-Col. Dimmock: Sarcoma of Ovary.
Mr. J. Barris: Intestinal Obstructian caused by a Fibromamyoma Uteri.
Mr. P. P. Cole: A Case of Pseudo Hermaphroditism.
Dr. H. N. Lewers: Sarcoma of the Vulva.
Dr. Clifford White: Sarcoma of the Vulva.
Mr. Douglas Drew: (1) A Case of Hermaphroditism; (2) Sarcoma of the Uterus.
Dr. G. F. Blacker: Sarcomatous Polypus of the Uterus.

Paper:
Dr. Archibald Donald and Dr. Fletcher Shaw: Symptoms and Treatment of Chronic Endometritis, with Special Reference to the After-results of Curettage.

NEUROLOGICAL SECTION (Hon. Secretaries—E. Farquhar Buzzard, Wilfred Harris): at 8.30 P.M.

Presidential Address:
Dr. J. A. Ormerod: Two Theories of Hysteria.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—L. Hemington Pegler, W. H. Kelson), at 11, Chandos-street, W.: at 5 P.M.

Opening Remarks by the President (Dr. P. Watson Williams).

Cases:
Will be shown by Dr. Dan McKenzie, Mr. Harold Barwell, Dr. StClair Thomson, Dr. Jobson Horne, Dr. Cyril Horsford, Dr. Scanes Spicer, Dr. William Hill, and others.

SECTION OF ANÆSTHETICS (Hon. Secretaries—R. W. Collum, Mrs. Dickinson Berry): at 8.30 P.M.

Paper:
Mr. A. L. Flemming: Prolonged Anæsthesia Maintained by Ether and Gas Alternately.

Demonstration:
Mr. J. F. Trewby: A New Inhaler for Administering Nitrous Oxide Gas by the Nasal Method.

RONTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY.—8.15 P.M., Dr. G. H. Rodman: Presidential Address.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Dr. Barnes: Motion—That Qualified Surgeon Dentists be admitted to the Membership of the Society. Clinical Cases.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersith.

FRIDAY.—8 P.M., Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY—5 P.M., Dr. G. N. Pitt: The Results of Bronchial Obstruction. (Bradshaw Lecture.)
THURSDAY.—5 P.M., Sir T. C. Allbutt, K.C.B.: Greek Medicine in Rome. (Fitz Patrick Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Rickets, Cretinism, &c, (Museum Demonstration.)
FRIDAY.—5 P.M., Prof. A. Keith: Specimens illustrating Acromegaly and Some Allied Conditions. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Dr. C. R. Box: Syphilitic Hemiplegia in Childhood.
TUESDAY.—4 P.M., Dr. E. Pritchard: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. E. Herman: Abortion.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Fitz Patrick Lectures

ON

GREEK MEDICINE IN ROME.

Delivered at the Royal College of Physicians of London

BY SIR T. CLIFFORD ALLBUTT, K.C.B., M.D. CANTAB., F.R.S.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

LECTURE I.

PRESIDENT AND FELLOWS,—My last lecture* ended with the name of Soranus, and concerning obstetrics.

SORANUS was of the sect of the Methodists, but was far too great a man to be enthralled in any sect. Galen, who angrily repudiated Methodism, yet spoke of Soranus with unwonted respect. The renown of this great physician, from the centuries of Tertullian and Augustine through the Middle Ages, rested chiefly in this field of medicine; but to confine his distinction to any one part of medicine would do him less than justice. Soranus, who received his medical training in the later Alexandria, was a great physician in all Medicine; and, as many of my colleagues are well aware, no inconsiderable part of his notable work on "Acute and Chronic Diseases" has survived in the transcript of Caelius Aurelianus, who lived 300 years later. Still upon the Gynæcology we may tarry for a moment, as upon this side of his work Ilberg has just published an interesting essay,[1] an essay which forms a part of the large and scholarly work upon medical classics undertaken by the school of Diels.

The enormous ascendency of Galen, his vast output in which he even surpassed that which amazes us in the writers on many subjects in the first two centuries of the Empire; his intricate and ardent dialectic, which endeared him to the logicians and rhetoricians of his own and many later centuries; his teleological philosophy, which endeared him to the Church; and, above all, the brilliancy and fertility of his genius, by overshadowing obscured and even effaced the traditions and documents of his predecessors. Lost in the glamour of Galen, in the Middle Ages even the invaluable Celsus was forgotten. Not only so, but the animosity of Galen against Methodism threw the work of this school into the greater neglect. Thus it was, as again in the time of the discovery of printing, that a turn of fashion brought destruction to many a precious manuscript. Yet if in the obliteration of his works Soranus was almost as unfortunate as Asclepiades, he was more fortunate in the upholding of his good name; in all later times he has been regarded as a great if half-forgotten physician. If, then, we have to appreciate the work of Soranus, we have not to refurbish his character.

FRAGMENTS OF SORANUS ON GYNÆCOLOGY.

Of his important work on Gynæcology but little survives, nothing directly; but by a Cuvierian process of piecing together fossil fragments Ilberg has attempted, not unsuccessfully, to discern and to rectify some farther part of the relics of Soranus concerning this subject.

In the Bibl. Nationale is a manuscript, dating from the end of the fifteenth century (Parisinus graecus, 2153), of a kind of Handbook or Articella, a compilation without author's name, the middle or gynæcological part of which is a document of 67 leaves, upon which is written in a rough hand, "Σωρανός ἐστιν." On the several attributions of the constituent parts of this handbook, which in the fifteenth and sixteenth centuries had a great vogue in the practice of midwifery, I cannot here dwell in detail; suffice it to say that their distribution is now more explicit. The first critical edition of the Parisinus, by Dietz, was posthumously published, without the advantage of the editor's own care, in 1838 as being, the whole of it, from the Περὶ γυναικείων πάθων of Soranus. But the part attributable to the master himself was less than half of it. Ermerins did something to discriminate its contents, especially in comparison with those excerpts of Soranus which are embedded in the XVIth or Gynæcological Book of the Ἰατρικὰ of Aetius, a compiler of the sixth century as yet imperfectly edited. But the Parisinus contains additions, both of sentences and of chapters, which are significant as to authenticity, and are also of substantial importance; especially those on diseases of children, and on anatomy and physiology. The Aetius chapters (XVI. 50–87) seem to have been, as it were, a canvas upon which certain "Soranea" were worked in.

The next important step in the reconstruction of Soranus was taken by Valentine Rose. In the fifteenth and sixteenth centuries a certain Latin book was familiarly known to obstetricians as the *Gynaecia Muscionis*. Its history is a curious one, for it is the Latin form of it which proves to be the original work, the earliest known copy being an illustrated MS. of the IXth–Xth century now at Brussels.[2] The Greek rendering, under the fancy ("mundgerecht") title of "Moschion," falsely supposed to be based on the "Genetia" of Caelius Aurelianus, and to be of the VIIIth–IXth century, is much later. It was the erroneous notion of its antiquity which Valentine Rose corrected in an able study (Soranus, 1882) wherein he proved the "Moschion" to be but a translation of Muscio, and—as Moschion—to have a pedigree not older than the fifteenth century; and, moreover, to be of very subordinate value. Many of the ignorances and errors of this "Graeculus" are set forth by Ilberg. Getting rid then of this Greek pastiche, it is on the Latin midwives' book that we are to fall back for such light as it may throw collaterally upon the Soranus from whose hands it was supposed to have come. Thus to verify the Soranus relics these relations had to be made clear.

Now "Muscio" professes to have had before him two works of Soranus, a brief and catechetical, and an ampler work. He followed in the main the briefer and more didactic of the two, but also he padded out his rendering from the larger treatise. Soranus, in what we know of him, was prone to be sententious, to utter maxims to be learned by rote; this we perceive, for instance, in the substantial fragments of the "Acute and Chronic Diseases" preserved by Caelius Aurelianus. There are similar reasons to suppose also that, after writing his larger books, he drew up a book of Responsiones or catechism.[3] Now, in these features of composition Muscio coincides likewise with Soranus as we know him from other sources. The illustrations probably belonged originally to the smaller or catechetical book of Soranus, and were reproduced to facilitate the abbreviation.[4] They have been carefully studied by many commentators, lately by Sudhoff.[5]

The outcome of this farther study of the Parisinus compilation Ilberg sums up as follows. Of the original date of it there is no evidence; the Byzantine physician put in nothing characteristic of himself or of his period. A tag from Meletius may well have been inserted later. It may have been written in the decadence of the seventh or in the awakening of the ninth century. The anonymous author had before him in its two forms the work of Soranus—Περὶ γυναικείων πάθων, and also the XVIth Book of Aetius; and these he undertook to blend into a new book. Passing over alteration of chapters, the scissors of the compiler were applied to what were probably four books of the original Soranus. Book I., though with some modification of form, he reproduced nearly in full. Book II. was also preserved, and its order better retained. Book III. was more destructively dealt with, and moreover, after the example of Aetius, suffered interpolations and corruptions. Book IV. suffered still worse things ("traurig ruinirt"); it was reduced for the most part to perverted scraps. On the whole, it would seem that the Aetius book was the framework of the compilation, and supplied, indeed, the greater part of it; and, as Ilberg remarks, compilers were far less scrupulous than transcribers.

Up to the time of Oribasius the texts of Soranus seem to have been in fair preservation; so that from this valuable

---

* THE LANCET, Nov. 27th, 1909, p. 1578.

[4] There is no difficulty about the date of such illustrations. There were illustrations in Vitruvius. At an earlier date Aristotle refers to σχήματα and διαγραφαί in the History of Animals; and at a later Galen seems to have produced diagrams (ὑποδείξεις διὰ γραμμῶν) of the muscles and nerves of the arm, and of optical phenomena. The Alexandrians produced many illustrations.

[5] Studien d. Gesch. de Med. IV.

compiler many smaller emendations and additions have been obtained. Probably Oribasius contains also more of Soranus, portions at present beyond identification, though some passages of the common Alexandrian tradition may have passed to Oribasius directly from Philumenos.

SORANUS AS PHYSICIAN AND SURGEON.

Of the traditions which bound Soranus to the earlier Alexandria, one of the chief was the works of Demetrius of Apamea, a disciple of Herophilus who flourished about 250 B.C., whose teaching, especially in respect of etiology, Soranus cites with admiration. It was the boast of the Methodists, indeed, especially of the more empirical section of them, that they looked *μόνον πρὸς τὸ πάρον*, for in their opinion to pry into causes led off to alien curiosity; while the only anatomy they required for clinical purposes (*χρηστομαθείας ἕνεκα*) was the state of constriction or relaxation of the tissues affected (*χαλᾶν ἢ στεγνοῦν*); thus for them immediate clinical observation was all in all, and normal physiology a matter of indifference. But it would have been surprising if, Methodist as he was, one standing in the following of Herophilus should have accepted the arid universals of that sect, regarded anatomy as *ἄχρηστος*, as ministering to mere curiosity, and dismissed the study of causes as otiose. In these respects, as in many others, Soranus, as Galen perceived, was greater than his school. The larger idea of molecular biology, and that of disease as a deflexion from the normal, were being degraded into the arid formulas of the later Methodists, a sterility which justly provoked the ire of Galen; and from their shackles Soranus did not shake himself free. He was, I think, more of a captive than Ilberg seems fully to admit,—to these empty abstractions, the *κοινότητες* of *strictum* and *laxum*, under which clinical diagnosis fell into little more than the dilemma of *στεγνοπαθοῦν καὶ 'ρευματιζόμενον ὀξέως ἢ χρονίως*. Still it is no less true that these views—these concentrations on *τὸ πάρον*—fastened attention upon the masterly clinical observations in which Celsus, Soranus, and Archigenes excelled. The capacity of Soranus as a surgeon we may recognise in his teaching on fractures and luxations as preserved in Aetius and Niketas. In Ilberg's words, then, Soranus "ist kein Toter"; both in learning and practice and in loyal regard to tradition he stands on the heights of ancient medicine. His disciples were taught not only "claudere librum ut cogitent," but also, and yet more, *claudere librum ut videant et curent*.

It is in his therapeutics that the methodist doctrines betray themselves unmistakeably, as in the ingenuity of local applications to command the permeability of the tissues of the parts affected. In his surgery we find Soranus cautious and conservative; he did not betake himself to operation until other means had failed.

As to his ethical attitude, which was honourable, Ilberg refers us to a paper of his own[6]—one to which I have not ready access—on *φθόρα*, i.e., the decision between the life of mother and child, as illustrated by the maxims of Soranus Aetius.

PNEUMATISM.

Passing, as needs must by leaps, from period to period, in the next place I propose to invite your consideration of the sect known as the Pneumatists, and of the doctrine and idealism of the Pneuma. I separate the history of the sect from the history of the idea, because as a sect the phase was brief and its doctrines inconsistent; though the idea is one which in manifold forms has dominated and animated the minds of men beyond the domination and beyond the inspiration of any other idea in physiology: and this with a fervency which has penetrated far beyond the limits of the biological sciences. Indeed, as we utter the word inspiration we feel that the glow of the spirit, which from the ancient legends of the creation of life to the messages of our modern ethereal telegraphy, from the hauntings of the Great Spirit in primeval man through the storms of superstition to the haven of the soul in his purer communion with the Divine, has moulded the whole story of man, and embedded itself even in his tongue. Inspiration is just air; but what air? What in air, or of it, can be fraught with creative power? and how can it endow the tabernacle of clay with energy, life, motion, and thought?

One of the most touching aspects of human life is the perennial warfare, the rage between the idealist and the man of affairs; nay, it is even of this war that tragedy and comedy are begotten. It is a materialist prophet of to-day who bewails "the untameable wildness of the good." This is the story of Paul before Festus; of Francis before Elias and the Pope; of the "Lady Helen of Troy pacing to and fro with a nosegay in her golden shawl" before Mrs. Elizabeth Fry; of Garibaldi before Cavour; and in comedy of Quixote before Sancho, or the modern curate preaching Tolstoy before his country rector. "Church," said Mr. Tulliver, "was one thing, common sense was another, and he wanted nobody to tell him what common sense was." The dilemma is *ambulando* insoluble.

And of this kind is the story of the great Ionian idealists, the philosophic dreamers before Hippocrates and Aristotle; and the story of the Greek speculative reason, touched with an oriental mysticism, before imperious Rome. A distinguished modern author of the extremer Western variety has lately reiterated with uncompromising emphasis that in the sphere of ideas we owe all we are worth to the Greeks, a claim, however, which cannot be admitted without profound qualification. The Greek was the prophet of the "*Via Media*"; but to the idealist the *via media* has always been detestable, as detestable to John Knox as to John Henry Newman. The achievement of the Greek was that the plane was so lofty on which the seer of both blended and integrated the ideal with the actual; that his *via media* was so high a mean between the imperative categories of the idealist and of the materialist. By an exquisite insight and tact he renounced not only much of the uses of the comfortable and pragmatic kind, but, as we perceive in Plato as well as in Aristotle, he definitely relinquished also the vision of some of the elements pertaining to the ideal society. The Greek saw "the untameable wildness of the good," saw it even with sympathy; but he saw also how much of it would not come into his picture.

The "practical" nature of Roman thought.—Now we observed last year that toward these horizons of blended material and spiritual discernment Rome had not a lofty outlook. We are told, and not without some congratulation, that Rome was too "practical" for such issues; that the average Roman was above all things the practical man. Well, were he as audaciously satisfied as Dr. Archimedes Silverpump of the Lycurgus House Academy, he had notwithstanding his enormous place in the world's history. Still it is true that his work, fundamentally necessary as it was, the necessary foundation upon which modern Europe should be built, was yet but a substructure, and the Roman a labourer to be dismissed when this task was done. And, as we observed also in last year's lectures, while the Roman pavior was wielding his beetle, while with plumb and square he was shaping and laying the great blocks for the edifice upon which we are designing and are building the superstructure, even then ideas could not sleep. We have seen how the leaven of alien minds in Rome was fermenting, expanding, and penetrating to the joints and marrow of her work; and, as it in mockery, displaying upon her sullen atmosphere phantoms of what after her was to be; even then Rome was not permitted to forget that man cannot live by bread alone; not even if the loaf be protected by the policeman. It is this untameableness of ideas, this unconquerable mind of man, which makes the fascination of our story of the Greeks in Rome, as it does of the history of the Jews, or of the ideas of the Jew, in barbarian and in modern Europe. For, if under other guises, the conflict of Mammon, of Pagan, of Jew, and of Christian was never keener or more searching than it is to-day.

Now, as in our own land we often congratulate ourselves—too often perhaps—on being above all things "practical" men, and as in respect of the function of Rome this term is often used as sufficient for all explanation, may we tarry for a moment to ask for some notion of its meaning? For instance, is Euston terminus more "practical" than the Pantheon? or the Pantheon more "practical" than Santa Sophia or the Parthenon? And if so, why and how so? To answer this question must we not consider which of these achievements will have the most abiding use for mankind? Furthermore, we might ask if the ideas of the order of Euston, or of an Atlantic steamship, exist for the sake of the ideas of the Parthenon, of Canterbury, or of William Wordsworth? Or conversely? We cannot pursue this train of thought, but we perceive that by "practical" in the Roman

[6] "Zur Gynaekologischen Ethik der Griechen" in the Archiv für Religionswissenschaft, xiii., 1910.

sense we mean the immediate needs, the things and devices of to-day as contrasted with things to come; or as an adept calculation and encountering of transient contingencies as contrasted with larger, future, and more consummate ends. While we admit, then, that Rome was laying the material bases of social order and culture, we perceive that with the issue of this material function her civic life began to decay; for to ends she had contributed little. And we are not surprised then to hear that the Greek too, not Aristotle only but Plato likewise, regarded himself as above all men practical; that in all the schools of ramifying philosophy the conscious, deliberate, and prophetic purpose of each was the art of life—the βίος τέλειος. Shall we not, then, consider how we defer to the Roman as conclusively the "practical" person; may we not have to describe him rather as the artisan of a material office, as the pioneer before the architect?

The prophetic genius of Ionia.—Now to return to the philosophers of the Homeric land; no work, ardent as it was, inspired as it was, could have seemed more visionary and less practical than theirs. In the later Attic reaction, the restraint of a more measured harmony, their exorbitant speculations seemed overwrought and in the void; Socrates explicitly repudiated their physics, and to this day they are too often regarded as vacuous bombinations. Yet to the prophetic genius of Ionia, the "*sapienza poetica*" of Vico's happy phrase,[7] we owe at least four cardinal ideas, ideas which lifted the earth into the universe, revealed the universal spirit, the creative process, and the universal order; the four master ideas which within my present limits I must indicate nominally as the Cosmic idea, the Dynamic idea of a Continuum of streaming and indestructible energy, the Atomic hypothesis, and the compound idea of Natural Law and of Evolution. And to these I might almost venture to add the idea of gravitation. As we glance at this childhood of science, idly noting perhaps little more than its obvious puerilities, we are apt to forget the ironical question, What is the use of a baby? Yet some further reflexion will make manifest to us, behind this inexperience, an insight and a grip of essential principles which 2000 years have enormously developed but hardly regenerated in principle. It is startling to feel how near us these great thinkers are; how much nearer than Abélard and Aquinas, when they unfurl the canopy of heaven into the air of infinity, when they prophesy of celestial and terrestrial physics, of natural law, of evolution from rudiments, of condensation and attenuation, of molecular energy, of formative combustion, and even of mind-stuff.

But to bring these radiant visions under some measure of realisation (πολησις), and to vindicate the values of medicine and natural science independent of philosophy, in the fifth and fourth centuries respectively two men as great, but of other gifts, arose—namely, Hippocrates and Aristotle. The reader of the greater Hippocratic treatises will find, as Gomperz has generously maintained, the door opened upon a way which to us has become so familiar that we find it difficult to understand how in its own day it revealed the growth of a method of thought and discovery wholly new to the world—namely, the scientific method, as contrasted with scientific imagination.[8]

Now who was this great Hippocrates, this prodigious man, and was it by the power of medicine that he was fashioned thus out of the visionaries of the age? That he did not stand alone, that he must himself have been the product of a great school and of a great tradition, our historical sense would bear witness. It is no barren fancy to associate the Father of Medicine in our imagination with the Father of History. Both inherited the luminous Ionian mind; and the author of Airs, Waters, and Places, cradled on the same enticing seas, had likewise travelled widely and observed shrewdly; both saw common things under the species of a large humanity. Indeed, the Hippocratic scriptures themselves also testify to a great school and a great tradition of medicine which, if sown and watered in a forgotten past, bore its golden fruit in Hippocrates, in Aristotle, and in the scientific schools of Alexandria.

In the anonymous Menonian MS. of London it would seem that Aristotle attributed a certain book of this heterogeneous Hippocratic collection—namely, the Περὶ φυσῶν—to Hippocrates himself; and it is evident that if we could fasten any one of these books upon Hippocrates we should have therein a clew to his personality, and to the authenticity of other books of the canon. Hitherto, as I said last year, we have assumed that certain works marked by breadth of view, scientific temper, and sagacity, seemed by these very qualities to proclaim themselves as from the hand of the great master himself. And perhaps this is not altogether to reason in a circle, for such qualities, by the witness of his contemporaries, were his. But, unhappily, these are not the qualities which mark the treatise Περὶ φυσῶν, a title difficult to translate into English, but which may be rendered *Concerning Airs*. Far indeed from breadth, precision, and wisdom, the Περὶ φυσῶν is a popular oration as windy in its rhetoric as in its subject-matter. We recognise in its affectations the rules of phrase, trope, antithesis, and cadence, which with a finer art were observed by all Greek rhetoricians, as, for example, in the masterly treatise of the fifth century, the Περὶ τέχνης of the same collection.[9] It is, in fact, an inferior product of the Stoical physiology afterwards, as a school in Rome, known as Pneumatism; and if Aristotle really did attribute it to Hippocrates—well, says Ilberg, so much the worse for the medicine he was taught in Stagira. But I must not occupy you with the pretentious banalities of the Π. φυσῶν;[10] I have alluded to this tract, as I might allude also to some sentences in the Περὶ τέχνης, only to indicate the prevalence through the Hippocratic period of the doctrines recognised later still as a school under the title of Pneumatism, doctrines which in Rome were taught by the interesting physician Athenaeus of whom I am to speak.

The origin of the idea of pneumatism.—In my remarks on this school, I must begin by acknowledging the debt which, in common with all students of the subject, I owe to Wellmann's essay on "Pneumatism and the Pneumatists."[11] Yet I trust that, although without it my own would have been very defective, this sketch may be no mere reproduction of Wellmann's work. Amid the manifold aspects and sects of Roman medicine I have chosen to solicit your attention at somewhat greater length upon Pneumatism, because among other qualities of interest its central idea seems to me to shadow forth what I have elsewhere ventured to describe as the pathetic quest for oxygen. In the history of opinion we have to beware not only of shaping the opinions of the past by our own, but also to take heed lest, while thus detaching ourselves as critics, and thus desiring to attribute to each of our ancient forerunners just his own uncoloured ideas, we discriminate them with distinctions to which he was a stranger. The ancients had not distinguished, disentangled, or differentiated concepts, or principles, so as to argue within and around them with the precision and discernment of later generations. In those times ideas were not so much mingled as inchoate, and still implicit together; their rudiments had not extricated themselves into separable strands. Ideas were nebulous, approximate, and blended. Logic came afterwards, only too soon, only too systematically; for many a century only to deprive the earlier speculations of their spontaneity and of their naivety, while masking with its wire grille the vacuity of fact and the lack of verification.

The origins of the idea known for a while as Pneumatism are lost in the backward of time. The soul itself was an air or vapour. Mr. Barnard Cook tells me that the goddess which escaped from the cleft skull of Zeus may be regarded as his soul. In early Indo-European religions the soul in both sexes was conceived as feminine; as, for instance, the Sirens, the Harpies, the Eumenides, and so forth. Thus from Zeus we move immediately to Ether (Αιθηρ), or ethereal essence, a dynamic conception having many qualities,[12] or

[7] For an interesting and discerning comparison of rational analysis with the instinctive, impersonal insight of myth and poetic tradition, often of deep intrinsic philosophical meaning, see Flint, Study of Vico, 1884.

[8] There is no writing extant which brings this new temper so impressively before us as the Hippocratic treatise on Ancient Medicine. Herein is set forth the way of experience, of careful observation of facts. And somewhat sharply controversial as it is against unbridled speculation, and the deductive application of philosophical ideas to the interpretation of natural phenomena, it, is yet interesting to note that this treatise is also of Ionian origin.

[9] Vide Theodor Gomperz, Die Apologie d. Heilkunst, 2nd edition, 1910.

[10] I have written more fully of this treatise in the Classical Review for 1910.

[11] Philologische Untersuchungen, xivtes Heft. Die Pneumatische Schule bis auf Archigenes; von Max Wellmann. Berlin, 1895.

[12] The element was not active primarily, it was but ποσότης; it was on its quickening into a quality (ποιότης) that it became creative. And it is to the qualities, says Wilamowitz, that the platonic term τὰ στοιχεῖα is properly applicable. The pneuma provided, as it were, the λόγος of this conversion. And as if this were not ingenious enough

developing into many; for the pneuma—if I may anticipate the use of this term—was imagined as a yet more primeval substance (Urkörper) out of which when fertilised by a seminal principle (σπερματικὸς λόγος) particulars emerged. Thus the idea of the pneuma contained more than the several notions of air, of vapour, of fire; it was a world force, a divine reason. And thus, as being in "conciliation" with nature, its works were interpreted teleologically; and in this connexion it was that pneumatism became allied to stoicism, an alliance at first sight unlikely, as one without radical coherence; but in consistency stoic physical teaching as a whole was lacking, being rather an eclectic array, a syncretism for pragmatic ends, than an organised philosophy.

It is to Galen, whose value as a source of medical history cannot in our dearth of sources be over-estimated, that we owe most of our knowledge of Pneumatism in its more developed doctrine. Our knowledge of the system is also enlarged by a pseudo-Galenic handbook, Ὅροι ἰατρικοί, supposed by Rose and by Diels to represent Athenaeus, as it observes his arrangement. But, being of later date, probably of the third century A.D., it contains more than this, and throws some light upon Agathinus, Archigenes—of whom I have more to say hereafter—Leonides and Heliodorus; and in the manner of the second century is a fusion or tesselation of pneumatism, methodism, and eclecticism. This treatise deals also with the pulse lore with which, as we shall see, the pneumatists made great play.

The doctrines of pneumatism.—To set forth the doctrines of Pneumatism, from their primeval sources to their completion, chronologically, and with due regard to their several exponents, would within our limits be impossible. I will try to sketch the history succinctly. In advancing then from the primeval ethereal essence (Σεὺς-ἀἰθηρ), we have glanced at an early division into active and passive, into primary force and primary substance, the conjugation and products of which opposites played a large part in much of the later philosophy, without as well as within pneumatist circles. And passing on to the farther evolution of these vapourous essences, we find them elaborated in Plato and Aristotle,[13] from whom the dynamic view of life was carried forward to Alexandria rather through Diocles[14] and the Sicilian School by which Plato was especially influenced, than on the Hippocratean tradition, which indeed was soon to petrify into maxims or "dogmatics." Now it is of peculiar interest to us as physiologists that an effort was made by these medical philosophers to conceive of a dynamic essence "between air and fire"; for here it is that we note the beginning of the pathetic quest for oxygen which, from Empedocles to Lavoisier, drove physicists, chemists, animists, and vitalists, like a gadfly.

I have already reminded you of the rapturous idea of flux revealed by Heraclitus. Worlds away was his rushing, teeming, manifold, many-coloured torrent of life from the grey motionless shadows of the Parmenidean unity. But we must drift down on these subtle airs to the Timaeus, whence, and from other sources, we learn that the whole apparatus of breathing was regarded as independent of the animal organisation; the "ζῶον" was already "πλάσθεν"—moulded into form—when this dynamic function was added to it.[15] The structure of the whole body being pervious to both air and fire, as the most subtle of all created things (πάντων γενῶν σμικρομερέστατον) fire drives the air through its pores; wherein we find an early allusion to respiration through the pores of the skin (διὰ μανῶν τῶν σαρκῶν), an ancient doctrine at least as old as Empedocles and probably older. Without going tediously into detail, Plato's conception was of a double cage of net or wicker, the outer containing air, the inner containing fire (as it were cages of carbonic acid and oxygen) with inlets to the bodily orifices, so that those agents by alternate inflation and depletion (ἔκπνόη and ἀναπνόη) should palpitate through the body. We start full; then the air, heated by the fiery envelope, drives by the nearest way through mouth and nostrils; then again, to avoid a vacuum, comes a compression (περίωσις), so that the air escapes through the tenuous interstices of the flesh (inspiration), and so onwards by oscillation (αἴωρα) through the blood-vessels (φλέβας) and the cavities (διὰ τῆς κοιλίας): "making its course from the inwards to the parts extreme." The corpse differs from the plastic but not yet breathing body in that both soul and "form" have escaped to their refuge (ὑποδοχή), and left the "matter," which they had temporarily impressed, inanimate. "To die is to be a counterfeit; for he is but the counterfeit of a man who hath not the life of a man," said another authority. Such in rough outline was the remarkable contemplation of these great thinkers upon that primeval miracle the respiration, the inhalation of life from the invisible circumambient ether, essence, air, spirit, soul. "And He breathed into his nostrils the breath of life, and man became a living soul."[16]

The next considerable step in medical pneumatism was the fusion or adaptation of this dynamic idea with that of the four elements or radical substances (ῥιζώματα) of Empedocles—fire, air, water, earth—termed the τὰ ἁπλᾶ or rational units, the creative qualities of which (ποιότητες) were hot, cold, moist, dry. This reconciliation seems to have been due chiefly to a certain Chrysippus, a younger contemporary of Aristotle, who may be taken as the philosophical founder of explicit pneumatism as interpreted long afterwards for medicine in Rome by Athenaeus. Although the very obscure treatise Περὶ πνεύματος is not authentic as a work of Aristotle himself, yet no inconsiderable portion of the doctrine, as we may note by the terminology, is Aristotelian.[17] Galen[18] speaks of Chrysippus as the father of the sect (πρόπαππος τῆς αἱρέσεως), but he attributes no small share of it also to the direct influence of Aristotle. The Chrysippus of whom I am speaking was clearly not Chrysippus the Stoic, who lived a century earlier; but this distinction does not quite satisfy for the identification of this renowned physician so frequently quoted by Galen. For it seems probable that in the later fourth and earlier third century there were in Alexandria at least two of the name, father and son. However, merging the lesser in the greater, the greater Chrysippus, who may have been the master of both Herophilus and Erasistratus—of Erasistratus, if not directly yet at any rate indirectly through Metrodorus—was himself of the Cnidian school of medicine, and a disciple of Eudoxus.[19] Although he had travelled much and learnt of many, he seems to have retained the Cnidian habit of minute observation of instant detail, of indifference to Coan reasoning upon remoter causes—such, for example, as on "airs, waters, and places"—and yet of academic logic. This sedulous obedience to fact may have fortified in Alexandria the bent inherited from Aristotle to anatomy, surgery, and symptomatology; and sowed there, moreover, the seeds of the subsequent empiricism and scepticism to which I have more than once referred. By tacking on many little points of agreement,[20] on some of which I shall touch incidentally, as well as by the new ideas with which he enriched medicine, we shall be able to trace the influence of Chrysippus into later times; as, for instance, in the use of herbs and in other notes of therapeutics, especially concerning venesection, on which practice, as I shall show presently, Chrysippus set himself against the whole of ancient medicine, and with the effect on later generations down to Galen, to which, in the history of Asclepiades, we gave some consideration last year. "Chrysippus the Cnidian," says Galen (XI., 150 and 252), "who displaced (ἐξελὼν) phlebotomy altogether from our means of cure."[21] But to this important matter I shall return hereafter in some reflections

---

the pneuma was itself regarded as consisting in three phases, ἕξις the grossest, φύσις the generative, and ψύχη the finest—sensation and thought. And above these was the ἡγεμονικόν, or ruling quality placed by Aristotle, Chrysippus, and Athenaeus in the heart; but by some pneumatists this will or mastery was placed in the brain; but how, said the rest, could it energise in the coolest part of the body?

13 On this period I am indebted to conversations with Professor Henry Jackson and to Mr. Barnard Cook's "Metaphysical Basis of Plato's Ethics," 1895.

14 Personally I am disposed to attribute the Περὶ φυσῶν to some follower of Diocles.

15 Tim. 78, c. &c. Body, matter, or substance is perhaps most readily defined for this argument as resistance—inertia; it lay between "void" on the one hand and "form" on the other.

16 It is worthy of remark that Lawrence Oliphant said, "The sense of union with Christ, of His living in us, was manifested, or became perceptible, in a physical sense, chiefly in changes of the natural respiration."

17 On this part of the subject I am indebted to an essay by Neustadt: Ps-Aristoteles, Περὶ πνεύματος, Hermes, 1909.

1 IV. 160; and five or six other passages noted by Neustadt.

19 In his earlier paper in Hermes (1900) Wellmann exposes a certain "chronologische Ungeheuerlichkeit," due to the confusion of the Alexandrian teacher with namesakes; and to his guidance I am here again indebted. I may add that Wellmann regards Chrysippus as directly the teacher also of Erasistratus.

20 Vide Wellmann's useful lists in Susemihl (loc. cit.).

21 Neustadt, loc. cit.

upon the story of the pulse. The works of Chrysippus were still extant in the time of Celsus.

Now I will pass quickly over most of the interminable stoical and more or less pneumatist dialectic, worthy of medieval times, recorded by Sextus Empiricus, Diogenes Laertius and otherwise, as to modes of generation from those units; how on the dominant idea of generation earth and water were passive substances (*παθητικά*), fire and air (*δραστικά*) were powers (*δυνάμεις*), and so forth; over much logic also as to fire, heat, air, and pneuma; as to rarity and density (Zeus); as to heat in organic and inorganic bodies respectively; how far—and this is most interesting—fire (or pneuma) was not always a separating agent, but, as in the technical arts (*θερμὸν τὸ ἐργαζόμενον*), might fuse, temper, construct, and modulate them (make rhythm); passages which remind us of the lofty vaunt of Prometheus—

> " ..... in the fiery flame that lends
> Its aid to every art." [22]

Fire, that is, might work either as an element (or substance, *ὕλη*) or as a tool (*ὄργανον*). And if with some thinkers pneuma was regarded as a kind of fire, with others it was regarded as a fifth element or *ἁπλόν*; in either case by their various mingling and the formative fire the several main tissues of the body (*ὁμοιομερῆ*), that is, bones, flesh, blood-vessels, &c., were evolved.[23] It was generally agreed at any rate that heat, to which at least pneuma could attach itself, was the demiurgic power, and thus that the innate pneuma (*σύμφυτον*)[24] by movement kindled the inward heat (*θέρμον ἔμφυτον*); and by its penetration fused the whole into integration, or uniform harmony (*ἕξις*), promoted growth and propagation (*φύσις*), by way of which thinking comes, "for vapour cannot think," and awakened thought (*ψύχη*); the heat being constantly moderated by respiration. The Sicilians, on the Pythagorean tradition, regarded the heart as the seat of this inner or governing (*ἡγεμονικὸν*) fire, an attribution which I need scarcely say was accepted in the main by Aristotle, and thence was handed down to medieval Europe. It is peculiarly interesting to us thus to trace the fifth element or quintessence through Aristotle to Harvey, who still conceived it as the universal principle of motion[25] animating all things from the starry sphere of the heavens to the tireless orbit of the heart. For of life the Aristotelian doctrine was that of the three spirits—the vegetative, the animal, and the vital—"the vital is begotten of the purest heart's blood, and conveys the glow of life through the other members, which gives them all the capabilities of action which emanate from the heart's vitality, the arteries serving for the transmission of this spirit to all the members"—

> " Spiritus intus alit, totamque infusus per artus
> Mens agitat molem, et magno se corpore miscet."
> —*Æneid*, VI., 726.

We perceive, then, that pneumatism was a much larger idea than animism, which in its peripatetic doctrine contemplated the vital principle under three particular forms. Pneuma is nearly identical with the primeval principle of *νοῦς* (Anaxagoras), an energising principle yet no metaphysical hypostasis, but something physical, the finest matter (ether) vibrating in and through all things, but most vivid in living things.

When Aristotle says, and says truly, that cold condenses (*πυκνοῖ*) and heat makes more permeable (*μανότερον*), we seem to be hovering about the edges of Methodism, and to apprehend how and where these outgrowths of doctrine branched away from each other. To the academic student it may seem perverse that with such features in common the various sects of which we are speaking kept so bitterly aloof, each within its own conventional palisade; but in our own day, with far less excuse, are not these tribal animosities still as fierce, almost as stubborn, as they were in certain Pneumatists who, according to Galen, put their sect before their country? Many of them, poor things, had no country; and the Pneumatists, in the breadth of their ruling idea, seem to us to have been more disposed than men of other sects to sympathise with alien opinion. Thus it was that many of the pneumatist school approached, or indeed joined hands with, the Eclectics; but in no period of culture has a consciously eclectic school found the inspiration of life; in all times the doctrines of such schools, like compromises in practical affairs, have formed a mosaic rather than an organic body or synthesis, and have proved therefore to be temporary accommodations, and seminally impotent.

Relations of pneumatism to other doctrines.—So far I have pursued the general story of these ideas without arranging them formally in medical schools, or attributing them exactly to their respective teachers, in order to set forth an explication of so much of the pneumatist doctrine as, with some considerable peripatetic infusion, brought this school of medicine into alliance with the philosophy of the Porch.[26] For, as I have hinted, it is rather surprising to us to find the quickening leaven of the pneuma so actively at work in association with the Stoics, for whom all emotion was a perversion or a defect of virtue. This inconsistency was not only felt by such later Stoics as Panaetius and Posidonius, but became a subject of apologetic. Diels, however, in his essay on the physical system of Straton, suggests, or rather points out, that the pneumatic doctrine descended to Medicine more directly through this peripatetic teacher to Erasistratus of Alexandria, and thence to Rome. It is in the pseudo-Aristotelian *Περὶ πνεύματος* that we first find the pneuma definitely accepted as a fifth elemental quality.[27] And we have seen that the undoubted influence of Chrysippus in the Alexandrian schools pointed to him as the moulder of the theory of Pneumatism. The testimony of Galen, as cited by Neustadt and others, is not inconsistent with this attribution to the Peripatetics, for he says repeatedly that Athenaeus drew freely upon Aristotle. Another most interesting link of the tradition we find again in Diogenes of Apollonia[28]—namely, that both Aristotle and Theophrastus avoided any radical distinction between pneuma as the original or even as the one primary element, in which thinking stuff was implicit, and out of which accordingly came order in the universe, and common air; though they soon entered into refinements, notably as concerning that vague but penetrating apprehension of oxygen—the "substance between air and fire"—on which I have already dwelt. More fancifully, airs might be drier or damper, hotter or colder, more attenuated (spirit) or condensing into phenomena; and so on. Thus Diogenes no doubt contributed to the rhetorical sophistry of which the pseudo-Hippocratic treatise *Περὶ φυσῶν*, and others like it, consist; a degradation of lofty and prophetic ideas into coarser notions of blasts and tensions of air compressing, expanding, shaping, or disintegrating an inert matter. Thus by ruder and coarser minds two great dynamic ideas—the pneumatic and the atomic hypotheses—were debased; while the sagacious and prudent clinics of Hippocrates were frittered away in frothy rhetoric, barren Methodism, or formal and arid Dogmatics. In the absence of sufficient tests of premises and of sources this lapse into sterility was perhaps inevitable; moreover, the Roman temper was for such thumb-rule formulas as Themison and the Empirics provided. It is true notwithstanding, as we shall see, for instance, in Aretaeus (or Archigenes), in Heliodorus, and in Galen, that beneath all this sophistry a substantial medical and surgical

ΠΡ. *ἀφ' ὅτου γε πολλὰς ἐκμαθήσονται τέχνας* (261–2).

[23] On the Homomeria, or kinds of structure, of Anaxagoras vide Lucret., I., 830 et seq.

[24] The Pneumatists proper (Athenaeus) identified the pneuma with the innate heat (*ἔμφυτον θέρμον*) as a single entity, and also, with Aristotle, accepted the heart as the seat of it (*τὸ ἡγεμονικόν*).

[25] In their several orbits or spheres (circular as being the most perfect form) whirled the sun, moon, and planets, while the outermost sphere of the fixed stars whirled round the others with an enormous velocity animated by the quintessence or ethereal fire. This universe, a plenum, spun in the infinite void. The expansive elements (fire, air), being centrifugal, and the heavier elements (water, earth), centripetal, the whole was balanced, though it is interesting to note that ultimately all things (even fire itself) tended towards the centre of the earth (gravitation).

[26] I cannot dwell here on the points of difference: such as that for the Peripatetics heat and cold were drastic, and dryness and moisture passive; that Athenaeus regarded these substances variably as sometimes matter, sometimes as forces; that substances or elements, as *ποσότητες*, were often confounded by the Stoics with their active qualities (*ποιότητες*); e.g., water with moisture, earth with dryness, and so on. Indeed, the Stoic hair-splittings amidst these permanent or interchangeable logical entities, as between *ποσότης* and *ποιότης*, for example, are to us intolerable, and were in respect even of their own time as vain as for his time the logomachies of Duns Scotus.

[27] In Galen's words (quoted Neustadt, loc. cit.): "*Περίττον παρεισάγει κατὰ τοὺς Στωικοὺς το διῆκον διὰ πάντων πνεῦμα.*"

art was making its way, propagated in the main by the stream of Alexandrian science from Empedocles, Hippocrates, and Aristotle.

THE ARISTOTELIAN INFLUENCE IN ALEXANDRIA.

In endeavouring to elucidate this propagation and course of scientific ideas after Polybus, Diocles, and Praxagoras through the schools of Alexandria to Rome I have mentioned the name of Straton. Unfortunately for the historian, the name of Straton, like that of Chrysippus, was attached to several individuals. Of these, one, namely, Straton, son of Arcesilaus, of Lampsacus, tutor of Ptolemy Philadelphus, succeeded Theophrastus (B.C. 288) as head of the Peripatetic School, and held this position for 18 years, when he was followed by Lycon. Now this was the Straton who devoted himself so assiduously to natural knowledge as to receive the cognomen of Physicus. And Cicero (Quaest. Acad.) upbraids him for so giving himself up to nature as to neglect the study of virtue. But there was also a Straton, the same or another, an eminent physician of the third century, who was associated with Erasistratus. He is important enough to receive frequent mention over the centuries from Themison and Soranus (who quotes him on prolapsus uteri) to Oribasius and Galen, and to Alexander and Aetius. He opposed venesection after the manner of his alleged pupil Erasistratus; he was the first physician, so far as we know, to describe elephantiasis; and Erotian quotes him as author of a lexicon of Hippocrates. Haeser seems to identify these two persons; Fuchs (in Puschmann) separates them. The unity or duality of person may be of no great importance, for, if two, they were both in the line of the same tradition; but the force and direction of Aristotelian influence is a question of the keenest interest. The Sicilian tradition was never free from magical bias, and the Platonic School, which was impressed by it, set back the inductive side of learning. If, like Bacon, Aristotle may seem never to have apprehended, as the Ionians seem to have done, the infinity of the scope and subjects of knowledge, yet by virtue of this very concentration he restored the method of research by the serial order of facts and, like John Hunter two thousand years later, he brought together a vast collection of facts, acquired in great part by personal experience, but also by cautious inquiry, not of philosophers but of practical men, such as fishermen and huntsmen. Now such, we are told, was the very influence which the efficient if ambiguous Straton carried to Alexandria. In his own work Straton attempted to base science on experiment, and in particular we learn that he made systematic experiments on a "vacuum." So also Aristotle's extensive dissections of animals must have forwarded the study of anatomy in Alexandria. Furthermore, we know that Aristotle collected a large library, and that it probably became the foundation of the Alexandrian. We know also that in collecting these books he did so with a view to a historical coördination of knowledge, for which end he organised writers in several departments: Eudemus was editor-in-chief; Menon compiled the medical literature; Theophrastus that of minerals, of physics, and of botany; Aristoxenus that of music. Sadly we deplore the utter destruction of all these documents. By certain words and phrases we may trace the passage of these ideas through the Alexandrian Schools, especially through Erasistratus down to Athenaeus, the last physician, as we have said, to build directly upon Aristotle. For example, in the meaning of nature (*φύσις*)—concerning which Athenaeus definitely cites Straton; in the several kinds of the soul; in the hegemony of the heart; and in the theory of generation we recognise Aristotle.

Unfortunately, hitherto the discoveries of papyri in Egypt have brought forth few ancient records of Alexandrian medicine.[29] However, in the British Museum is a papyrus, apparently of just pre-Galenic date (noted by Mr. Kenyon in the *Classical Review* for 1892), which deals with certain points in dispute between the followers of Herophilus and Erasistratus. And Karl Sudhoff (Leipzig, 1909) has recently collected many interesting notes concerning drugs, customs, diet, and baths; and on temple and hospital matters: but no fragment of any great writer, nor any illumination of the history of ideas, has turned up as yet.

From such sources as we have, we learn that in the period of comparative peace which ensued in Alexandria after the internecine strife of the Diadochi until the expulsion of the physicians and the *savants* to the islands and Asia Minor from Alexandria by Ptolemy VII. (Physkon), a strange contrast to his predecessors, and before the diversion of the main stream of culture from Alexandria to Rome, burst forth that brilliant school of which we know so much by the glory of its notable achievements and so little by its documents. Moreover, under the Empire, and even in the later years of the Republic, the intercourse between the two cities both in trade and culture had become easy and continual. Celsus, for instance, in his therapeutical advice to consumptives, speaks of the voyage from Italy to Alexandria, even in the petty craft of those days, as "aptissime." In Alexandria then Hellenism had its fling, touched however more and more by Oriental influences, especially of that learned and ingenious race the Jews[30] and Syrians, of whom even then there were many in the city; influences which a little later, in the Neo-Platonic and Christian Schools, became potent, and even ascendant, down to the second great fire of the Alexandrian libraries in the fourth century.

We have seen, then, that the powerful and insatiable mind of the Greek from Anaximander to Plato, before the discipline of observation and analysis initiated by Hippocrates and Aristotle, had achieved certain general ideas of cosmic scope and significance. These ideas once apprehended, the framework of orderly knowledge had to be built up by more laborious methods. The difficulty then lay in the gearing of this tremendous thinking engine to practical work. While unharnessed, it spun about itself with enormous velocity, weaving out of its own dust what Francis Bacon called its cobwebs. These buzzing and ineffectual revolutions are almost more audible to us in the first centuries after Christ than in the thirteenth. For a season in Alexandria this tremendous energy was buckled to the real work of spinning webs, not of notions only, but of facts—of things, that is, which had happened, which were happening, and which experimentally might be made to happen. And in the Aristotelian tradition we know how brilliant were the results of these Alexandrian scientists, not only in celestial and terrestrial physics, but also in biology. For in this College the names of the great anatomists Herophilus and Erasistratus are even more familiar to us than those of Hipparchus, Archimedes, and Heron.

ALEXANDRIAN MEDICINE.

But to proceed with the sketch, so far as relics and fragments enable us, of those features of Alexandrian medicine which reappear in Roman medicine, and in our present concern with the Pneumatists. Speaking very generally, of the two great anatomists, Herophilus—one of whose masters was the Coan Praxagoras, led more directly from the Hippocrateans to Galen; Erasistratus from Cnidus to the Methodists and Pneumatists. And we can get a little nearer, perhaps, to the facts than this, though the respective disciples, or nominal disciples, of these masters perplex the modern historian by their manifold inconsistencies, vagaries in which the Herophileans particularly erred, even forfeiting the birthright of their school by shirking its anatomy and, with the frowardness of the Christians after them, dissipating the master's teaching in sophistries, elaborating a wiredrawn dogmatic system upon the flimsy foundation of glosses and commentaries on the texts then intact in the vast libraries of their city.[31] The Erasistrateans were more steadfast; they kept closer to their dootrine, and seem to have adopted much of the teaching of Straton the Aristotelean; they kept up at any rate some anatomy even down to the second century A.D. (Galen), and on their empirical side did better service than their dogmatising rivals.[32] And accordingly the Erasistratean School on the whole prevailed.

Herophilus, born at Chalcedon, lived and worked in

[29] Even of later date the medical finds are scanty. Meyerhof and Pflüger discovered in a library in Cairo some unknown MSS. on eye diseases of Arabian origin, and Meyerhof adverts to such relics in Damascus and Constantinople. These may prove to be translations of older treatises.

[30] It is said that in the reign of Augustus there were a million Jews in Alexandria; and we know there were Jewish physicians in the first century A.D.

[31] The name of Dogmatists was given to this school, if I remember right, by Galen. In working rather by the letter than in the spirit of their great founder, Hippocrates, they became the Pharisees of Ancient Medicine, as in after time were the Galenists.

[32] Besides the historical treatises already cited I am, in what follows, indebted also to Susemihl's Gesch. d. Griech. Litt. in der Alexandrinerzeit, Leipzig, 1891. This scholar at any rate perceived that from a history of culture Medicine could not be omitted. The medical sections are in great part from the pen of Wellmann.

Alexandria under the first, and perhaps in part under the second Ptolemy. In the eastward expansion of Greek scientific culture his doctrines were carried to Pergamon, and later to Laodicea. It is worth noting, in respect of the tradition leading down to Galen, that under the Attalid kings Pergamon was, at some interval, comparable in culture even with Alexandria; and schools were perpetuated there till Galen's time, although apparently with some decline; for we are told that when in Cæsar's campaign the library of the museum—not of the Serapeum—was burned, the Pergamene library was brought to Alexandria, only at a later time to be destroyed, with the Serapean, by religious fanatics. The school of Smyrna, on the other hand, by way of which, as we shall see, the prescription of wine as a medicine probably reached Asclepiades and Athenaeus, was founded, as we learn on the contemporary authority of Strabo, in the first century B C., by Hikesios, and he was an Erasistratean.[33] But to return to Herophilus; Haeser reminds us that, great as were his researches in anatomy, especially as regards the nervous system, yet before him Praxagoras seems to have made no inconsiderable advances in this study. He had distinguished, for instance, between the motor and the sensory nerves, although he presumed that the sensory nerves arose "in the centre of feeling—the heart." But over the earlier schools,[34] as also over Galen and the later, the Alexandrians had the incalculable advantage of dissecting the body of man.[35] Herophilus advanced to the demonstration of the origin and course of the nerves from the brain and spinal cord,[36] and described many of the parts of the brain, including the meninges; and he it was who recognised this noble member—hitherto regarded merely as a refrigerator for the inward heat—as the source of sensation and of volition. On his description of the liver, pancreas, chyle-vessels, and many other members, descriptions new in part, in part enlargements of previous knowledge, I cannot now dwell; but to his views of the circulation I shall return presently, when we come to discuss the pulse lore of this period and of the Roman pneumatists. Herophilus probably described the anatomy of the eye, as we know from Aetius that he wrote a treatise Περὶ ὀφθαλμῶν. To this great and precise observer Galen was deeply indebted; yet these Alexandrian anatomists never cleared up the confusion under the name νεῦρα. They still regarded nerves and tendons as varieties of one kind; varieties because they perceived that the nerves came from the brain and spine, but the tendons from the bones and muscles.[37] As a physician Herophilus, in opposition to Erasistratus, clung to the four humours of Hippocratic tradition, and opposed him furthermore in matters of pharmacy, dietetics, and hygiene; subjects with which he dealt at large in a work Περὶ αἰτιῶν.[38]

It would have been well if medical science could have continued patiently on these more positive, although it must be confessed still somewhat nugatory, methods. It has been the trial of Medicine that while, as compared on the one hand with the no less complex but far more accessible phenomena of politics, and on the other with the far less complex phenomena of the physical sciences, it has stood in respect of the difficulty and inaccessibility of its knowledge, and stands still, at an enormous disadvantage; yet, in no unnatural impatience with these perennial bafflings and obscurities, the moan of suffering men and women and the poignant misery of the child have ever driven us into action, however blind, however premature. Remedies, orthodox, empirical or quackish, remedies one way or another, and by whatsoever means, have always been imperiously demanded of us. And, as nowadays the modern physician cannot wait for pharmacology which seems to him, and not untruly, to be the tortoise behind the hare of empirical practice, so after a like manner we may imagine the impatience of Alexandrian physicians and sick with the pursuit of anatomy. Except in respect of surgery, the lost anatomical treatises of Herophilus himself could have contained but little of any immediate application to inner medicine. Such then in the middle of the third century B.C. was the ground in which, in spite of its scientific spirit, or perhaps engendered by it, empiricism and medical infidelity would readily spring up and, gyrating in the void of positive knowledge, would, and did, give rise to weary and endless disputes and logomachies—*Federkriege*, as Susemihl calls them. Professing much reverence for Hippocrates, physicians broke loose not only from anatomy but also from the Hippocratic rational sagacity. In the third century B.C., as we learn from that earliest essay in medical criticism the Preface of Celsus, and from other sources, Philinus of Cos,[39] the reputed founder in Alexandria of the Empirical School, and Serapion, who harshly straitened it, instituted the schism in which walked with more or less discernment their eminent successors, such as Apollonius of Antioch, Herakleides of Tarentum (whom Soranus calls the most persuasive of them all), Menodotus, and Sextus Empiricus.

Towards the end of the second century B.C., under the evil rule of Ptolemy Physkon, Alexandrian science began to dwindle. Hipparchus, who had flourished about the middle of that century, was the last of the great originating minds. Then the disinterested search after knowledge for its own sake dropped into an industrious and respectable assiduity; as into the technical furtherance of the crafts, especially of agriculture. Accordingly, we find then the beginnings of those summaries and compilations which, admirable as they were in Varro and Celsus—two of the most scientific of the Romans—dogged the retreating footsteps of Urania. Thus the field was left open for astrological phantasies and for marvels of zoology which began to creep in from the East, and, flourishing in Aelian, spread themselves through the bestiaries and herbles of the Middle Ages.

After this introduction concerning the history of the Pneumatist idea, it is convenient to illustrate its application to Medicine by some story of the chief medical teachers of the pneumatic school so far as we know them. However far-reaching, even perennial, as was the pneumatic doctrine, I repeat that pneumatism, as a medical sect, was of brief duration; and for the most part its adherents are now no more than names to us. I propose therefore to speak more particularly of two only—of Athenaeus, the formal founder of this school in Rome, and Archigenes, who, if an Eclectic, came forth from the Pneumatist School.

ATHENAEUS.

Athenaeus was one of the most interesting of the Romano-Greek physicians; Diels, in his essay on the physical system of Straton, emphasises the doxographical importance of Athenaeus, who nevertheless adopted and formed his opinions with much critical judgment. As to his date, Athenaeus of Attalia, who, like most of the Roman physicians, emigrated thither from the colleges of the wealthy Hellenic cities of Asia Minor, was unknown to Celsus, who lived in the days of Tiberius and to whom Methodism was known; but his works were well known to Galen, who cites him frequently and in terms of much respect as an author and *savant*. We may assume then, if perhaps he was born under Tiberius, that he flourished in the reign of Claudius. Athenaeus seems to have perceived how Methodism, in the sense of the atomic physiology, was even then withering; in practice it had dried up into two or three abstract maxims or common rules (κοινότητες); whilst its Epicurean philosophy was giving way in Rome to Stoicism. Thus intelligent men felt something more was wanted, and pneumatism, coming as it did in the tradition of the elder medicine—Sicilian, as we have seen, as well as Coan and Alexandrian—and in alliance with the ascendant stoicism, offered to fill the want. Athenaeus, therefore, had a large

[33] Strabo, xii., 580.

[34] That is speaking generally. Galen credits Diocles with some knowledge of anatomy, and there is reason to suppose that both this physician and Praxagoras, and so presumably some others, had dissected the human body. But in Alexandria there was an Anatomical Institute in which human bodies, as Galen says plainly concerning Herophilus, were dissected. (II. 895; "οὐκ ἐπὶ ἀλόγων ζώων καθάπερ οἱ πολλοί, ἀλλ' ἐπ' αὐτῶν τῶν ἀνθρώπων πεπονήμενος."

[35] Much more evidence would be necessary to compel us to believe the malignant insinuation of Tertullian that these anatomists opened the bodies of living men (criminals). Such brutality not alien to the Roman was foreign to the Greek.

[36] Galen, viii., 212.

[37] Cf. Daremberg's edition of Rufus.

[38] A certain Heracleides Erythraeus, lauded by Galen, a contemporary of Strabo about the Christian Era (placed by error in Haeser I see in the third century B.C.; there were three or four physicians of the name) wrote a long treatise on the "sect" (αἵρεσις) of Herophilus, but unfortunately nothing of it remains.

[39] We have to regret our ignorance concerning this considerable person; almost all else we know is that he wrote glosses on his distinguished compatriot before Erotian. The Empirics boasted of an heretical descent from Akron of Agrigentum (fifth century B.C.), an eminent physician contemporary with Empedocles. It is not impossible that the hazy science of the Sicilian School may have instigated such a reaction, but we have no evidence of it.

school or following in Rome. Indeed, pneumatism, as we have seen, represented a physiological principle of a kind so attractive that, under the phases of many schools, it survived in its essence until the eighteenth century. Athenaeus wrote a large and important work, Περὶ βοηθημάτων, which probably dealt with all departments of medicine. Unfortunately, this work has almost wholly perished; for what we know of Athenaeus we are dependent upon some fragments surviving in Oribasius, and upon some allusions by other authors. These relics suffice, however, to indicate that Athenaeus was a clear and accurate observer, apt in reflection and criticism, and wise in philosophy. To these gifts he added a large and various learning spiced with a shrewd irony. Athenaeus, like such later pneumatists, or eclectic pneumatists, as Herodotus, Archigenes, Leonides, Heliodorus, was a good surgeon. Moreover, the school was not clinical only. Besides its considerable therapeutical content, it taught also (as in the II. βοηθημάτων) an elaborate physiology and pathology which, within my present limits, I may be able to illustrate by a few references, especially by its teaching concerning the pulse.[40]

Athenaeus, who did much to weld together philosophy and practical medicine, apportioned the sphere or faculty of medicine into five divisions. The first was physiology, which for him was the essential foundation; and therein he made a great advance upon the methodists and the empirics. Of his next or second division, that of pathology, but little is known directly; yet we incur little error in interpreting the pathology of the master by that of his successor Archigenes. The main feature of his pathology, that upon which I would dwell for a moment, was the study of the causes of disease; for herein the school returned to the sounder tradition of Hippocrates, avoiding on the one hand the facile and jejune etiology of the methodists, and on the other the narrow concentration of the Empirics upon superficial and immediate antecedents. Of the logical classification of causes we read in Galen enough and to spare; and we of to-day in our array of causes are still somewhat given to outworn categories, such as the *predisposing*, the *exciting*, and so on. In Rome, from the time of Asclepiades, the sects which did not ignore the wider causes with moderation divided them into three classes at least, according to their nearness or remoteness in the series of antecedents. Thus Athenaeus did not expatiate in a wilderness of logical but unnatural categories. But the Pneumatists conveniently distinguished *αἰτία* from *διάθεσις*, by which they signified all which pertains to the conditions of the disease in the individual. Disease (*νόσος*) was the dyscrasia; *πάθος* was used variably as the lesion or as the functional disarray, fever, for instance, as abstracted from symptoms of fever.[41] *Συμπτώματα* were the consequences of the dyscrasia. The dyscrasia, a perversion of health (eucrasia)—the ancients perceived in these rhetorical antitheses substantial as well as verbal values—was for the genuine pneumatist a failing or taint of the pneuma, and to be counteracted by marshalling against it the contrary quality—as cold against fever, and so on; so that, as we shall see, physical means of cure prevailed with this school, such as diet adapted to the several seasons, clothing, exercises, waters, and so on. The fusion of their vitalistic pathology with the humoral, which for clearness' sake we are disregarding in this lecture,[42] was in its completion the task of Galen. By him the soul, or vital dynamic, in its three kinds—the natural, the animal, and the psychical soul—and the qualities of the elements were harmonised so far as logic could harmonise them; for instance, phlegm was akin to moisture, yellow bile to fire, black bile (spleen) to earth, and so on, the qualities being mixed in the blood. But it would be futile to enter farther into these logical permutations; I have said enough to give a notion of their method. It is, perhaps, more interesting to perceive how in certain ways Athenaeus and the pneumatists went back to Hippocrates. Thus I have touched upon their observation of climates and waters. The third pneumatist division was Dietetics; then came Materia Medica; and fifthly and lastly Therapeutics, a title with a larger content than is usual with us, and almost signifying clinical practice.

GROWTH OF POLYPHARMACY.

The vast commerce of the Ptolemies, and in some measure no doubt the lore of Pharaonic Egypt, had flooded the markets of Alexandria with quantities of new drugs. One writes to a friend to send him good quality of drugs "lest he do otherwise and send him stale stuff which will not pass muster in Alexandria,"[43] &c., and the keen inquiry for them was far more than the legitimate demand of the medical practitioner. For with the treatise of Theophrastus Περὶ τῶν δακετῶν καὶ βλητικῶν, as one may approximately say, began the prodigious and diabolical literature on the art and mystery of poisons and antidotes in which, not always without the aid of medical accomplices, kings and nobles of the empire and its principalities, and after them popes and cardinals of the Church, were the experts. And, indeed, the bent of the Herophileans, onward to Galen himself and the Galenists (Andreas, Krateuas, Apollonius Mys, Zopyrus), was to polypharmacy. In the decadence of Alexandrian science and society this gross propensity increased and multiplied; and under the influence of perfidious potentates, such as Mithridates,[44] Nicomedes, and Attalus, attained to an almost grotesque infamy. Under the foul accumulations of panaceas, mithridatics and cosmetics, elaborated with a perverse and loathsome ingenuity,[45] medicine was oppressed and almost suffocated; and the habit of heaping up ingredients made its way into the compounding of legitimate prescriptions. Thus to build up a huge and conglomerate bolus or potion became the ambition of the doctor, and the faith and consolation of the patient. If your liver is getting impatient, writes Juvenal in the XIIIth Satire, "seek Archigenes as fast as you can, and buy of him the composition of Mithridates, and you will live to eat figs and gather roses another year."[46]

THE TRAUMATIC NEUROSES.

BY THOMAS R. GLYNN, M.D. LOND., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, UNIVERSITY OF LIVERPOOL; CONSULTING PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL.

I USE the term traumatic neurosis in a limited sense, to embrace only neurasthenia and hysteria resulting from a traumatism, either by reason of the physical injury or the emotional disturbance that may attend it. Other neuroses, as insanity and epilepsy, which more rarely follow shock, are, therefore, not included in the term.

Erichsen in 1864 described the nervous troubles that at times follow accidents, and as these disorders frequently succeeded casualties on railways the term "railway spine" came to be generally adopted for them, the condition being ascribed to slight lesions, leading to chronic inflammation of the spinal cord or its membranes. Westphal and Leyden adopted the same view.

Russell Reynolds was the first to recognise the functional nature of the symptoms of the so-called "railway spine," for he held that the troubles of sensibility, the motor paralyses and spasms, were "dependent on idea." Oppenheim and Thomson adopted Reynolds's view and invented the term "traumatic neurosis," affirming that the nervous disturbance excited by injuries was of a definite and specific character. Two American physicians, Walton and Putman, pointed out that the symptoms of railway spine were indicative of cerebral rather than spinal disturbance. They therefore held that the term "railway brain" was more appropriate than "railway spine"; at the same time they regarded the cerebral symptoms as largely functional and akin to those of hysteria.

It was the more pronounced consequences of traumatisms

---

[40] In what follows I am indebted especially to Daremberg's Oribasius and Rufus, Wellmann's article on "Philumenos Hermes," 1908, and on "Ancient Medical History," Hermes, 1900, and continually, of course, to his "Essay on the Pneumatists." Nor must our general debt to Diels be forgotten.

[41] Herophilus pointed out that certain *πάθοι* might be natural (*κατὰ φύσιν*), such as childbirth or the secretion of milk; others unnatural (*παρα φύσιν*), such as fever. Still *πάθος* was often used in equivalence with *νόσος*, especially perhaps by the methodists (e.g., *ἡ παθητικὴ στέγνωσις*, &c.).

[42] We find the humoral pathology as far back as Herodotus, who tells how (IV., 187) the Lybian shepherds used to burn the veins on the vertex or temples of their children to prevent fluxions of rheum (*κατάρρεον φλέγμα*).

[43] Milligan, Sel. Greek Papyri, 1910, p. 58.

[44] The locus classicus of this treacherous lore is the twenty-fifth chapter of Pliny (N.H.). Krateuas probably worked under the patronage of Mithridates (cf. new ed. by Wellman, 1897).

[45] Among many other such books see Das Gift in der ..... antiken Literatur. By Dr. Erich Harnack of Halle. Leipzig, 1908.

[46] We note here that Archigenes sold the remedies himself.

that attracted the notice of all these observers—the hysterical spines and joints and the paralyses; the less evident result of nervous shock—neurasthenia—was at this period overlooked. Hence the victims of traumatic neurasthenia were likely to meet with little consideration.

Herbert Page[1] in 1885 was the first to recognise that traumatisms might be followed by symptoms of neurasthenia as well as by those of hysteria. Charcot in 1888 confirmed these conclusions, and by clearly differentiating the various symptoms of hysteria and neurasthenia rendered it possible to attain precision in the diagnosis of these affections. He also demonstrated that Oppenheim's traumatic neurosis was in no sense a specific affection, but that its symptoms were identical with those of hysteria and neurasthenia in combination.

The term traumatic neurasthenia is, in my opinion, frequently misused, not only by medical witnesses but by medical writers, it being applied to cases where the symptoms of hysteria are associated with, and perhaps preponderate over, those of neurasthenia. Its use is, perhaps, legitimate in a court of law, as the word neurasthenia has come to be recognised by lawyers as indicative of a definite disorder produced by accidents, and, on the other hand, the term hysteria to the unprofessional is suggestive of malingering.

The neurosis excited by traumatisms is usually a hystero-neurasthenia, and to overlook this fact is unscientific and leads to the confusion of the characteristics of the two diseases, inasmuch as symptoms are set down to neurasthenia which do not belong to the affection. For example, a recent writer on "traumatic neurasthenia" states that in this disorder the fields of vision are almost always restricted, the knee-jerks exaggerated and the plantar reflexes absent—all diagnostic signs of hysteria and not of neurasthenia.

In neurasthenia the symptoms are almost entirely subjective, and therefore capable of being feigned. Their value as indications of disease depends largely on the estimation formed of the veracity of the individual under examination. In such circumstances it is only likely that the opinion of medical witnesses on opposite sides should be at variance. In hysteria, however, there are many objective signs ready to be brought to light on careful examination—stigmata that furnish evidence of a decisive and positive character.

Genuine cases of traumatic nervous trouble, in the absence of careful clinical investigation, may not be treated with due consideration, and especially is this likely in the absence perhaps of all signs of physical injury or of any appearance of ill-health; for in these circumstances a suspicion is awakened in the minds of lawyers and juries that the sufferings and incapacity are mythical—a suspicion which is strengthened if it should appear that the litigant is capable of seeking diversion but not of resuming work.

It is the duty of a medical witness to search for any indications of disease that may be present, to note whether the statements of the individual under examination are consistent or otherwise. To conduct such an investigation intelligently he must be familiar with the features of the neuroses under consideration. I need hardly say that the medical witness should confine his evidence to facts. He should neither belittle symptoms nor exaggerate them; he should not become a partisan or a special pleader, nor allow sympathy to bias his judgment. Owing to the difficulty that is usually experienced in estimating the exact extent or possible duration of the incapacity in any case, should such exist, there is room for difference of opinion among medical witnesses—a disagreement which is made more divergent under skilful cross-examination.

Some physicians hold that neurasthenia, like hysteria, is a purely psychical malady—a disease of imagination. Dejerine and Dubois adopt this view. Bernheim, too, considers what he calls "false neurasthenia" to be of similar origin. It seems, however, unnecessary to invoke psychic intervention to account for the phenomena of neurasthenia when in every instance the disorder is found to be produced by such causes as the depressing emotions, overwork, dyspepsia, exhausting illness, and intoxications tending to lead to nervous exhaustion. Moreover, in so far as the muscular system is concerned the impairment of energy has been demonstrated by the use of the ergograph and by the experiments of Münsterberg.[2] Granting that these affections are disorders of imagination, it is illogical to conclude that the victims of a traumatic neurosis are impostors; surely the position adopted by G. Braun[3] is unwarranted: "That which in medico-legal work is called a traumatic neurosis would be regarded in ordinary life as a fraud."

The symptoms of neurasthenia and hysteria, whether they follow fright or injury or are developed in some other way, are equally characteristic, and these characteristic symptoms are met with as a consequence of traumatisms, whether the subjects of such traumatisms are or are not seeking compensation. It is hardly necessary to insist on this point, but I may refer to one case. A foreman in a foundry was struck on the forehead and knocked down. He got up and though suffering from headache and nausea remained at work. Fourteen days after, as he continued to feel ill, he consulted a medical man who advised rest and sent him to a hydropathic establishment for baths and massage. He derived little benefit and at the end of three weeks returned to work. When I saw him seven months after the accident he was suffering from pronounced neurasthenia, with a very irregular pulse and palpitation. With the exception of the brief holiday mentioned, he had not absented himself from his duties, nor had he thought of claiming compensation.

Hysteria, indeed, originates in auto-suggestion, and the associated physical troubles are due to the projection outwards of psychical images. The physical phenomena are, therefore, dependent on the mental state. On the contrary, in neurasthenia—if we accept the ordinary theory of its nature—the mental attitude is the reflex of the physical condition. For example, the muscular weakness gives rise to the sense of fatigue and repugnance to effort. The disturbances involving the organic functions being reflected on the brain occasion sadness, weariness, pessimism, and vague ideas of impending trouble. Although auto-suggestion may give to neurasthenia the aspect of hysteria it is in its essence a physical rather than a psychical malady. In non-traumatic cases of neurasthenia and hysteria we are generally able to trace a predisposition in the family history, in indications of a tendency to rheumatism, gout, tuberculosis, intemperance, or to functional or organic nervous diseases. In traumatic cases, however, great difficulty is usually met with in obtaining a reliable family history. I have suspected that intemperance in the parents might in many instances explain the exceptional vulnerability of the nervous system, but have failed to satisfy myself that such was the case.

The same difficulty is met with in regard to the personal history when seeking for evidence of a neurotic tendency, the victim of an accident usually asserting that he had never been ill before he met with the accident. I noted the signs of hereditary degeneracy in 8 out of my 40 cases—in jug-handle ears, asymmetry of face, and poor physical development in other directions. The man whose case I have just referred to had a congenital squint with defective vision of one eye, ill-developed ears, and irregular teeth. I had seen him with Dr. C. J. Mouncey of Earlestown eight years previously for idiopathic dilatation of the stomach and neurasthenia. At the time of the accident he had been well for some years.

A predisposing cause is probably often to be found in a weakened nervous organisation, brought about by the abuse of tobacco and alcohol, and further exhausted by unhealthy or arduous occupations and unhygienic surroundings. Some idea of the frequency with which the traumatic neuroses follow accidents may be obtained from the statistics given by Dr. R. J. Collie in a paper on the Workmen's Compensation Act, 1906. In 458 cases of accidents referred to him by the London County Council, he met with 24 cases of traumatic neurasthenia—a comparatively small number, and in its paucity emphasising the fact that some other agent besides the shock of an injury determines the development of the neurosis in question. This other contributory cause is predisposition. The severity of a traumatic neurosis, as a rule, bears no relation to the extent of the lesion that preceded it, its intensity depending rather on the constitution of the victim of the accident, and on the degree of emotional shock attending it.

[2] See Psychologie des Neurasthéniques, Dr. P. Harlenberg, p. 28.

[3] Prager Medizinische Wochenschrift, 1907, and the Medical Chronicle, July, 1907.

Emotional disturbance probably plays a more important part in the production of the traumatic neurosis than physical injury. A depressing emotion, such as terror, may in itself give rise to a hysteria or neurasthenia, and instances are not infrequently met with where these disorders have been excited by accidents which, though trivial, have occasioned much apprehension.

Sometimes the victims of violence cannot experience any emotion before or at the time of the accident: it is too sudden. Take, for instance, the case of a man who is instantaneously rendered unconscious by a blow on the head from a falling hammer. In such instances emotional disturbances in the form of worry and anxiety operate after the infliction of the traumatism, their pernicious action being increased in the event of sleeplessness and pain. Nervous shock produced by fright cannot operate when the injury is unexpected and causes sudden insensibility; and yet blows on the head are, I think, more often than other forms of injury followed by functional nervous trouble.

The most severe cases of hystero-neurasthenia that I have recently met with have followed blows on the head. One man fell off his bicycle on his head 18 months ago and was unconscious for three weeks. He is now, in spite of hospital treatment, a confirmed hystero-neurasthenic and quite disabled. The other, a patient of Dr. W. Macvie, besides an injury to the head suffered also from a broken arm and leg; he has been utterly disabled by hystero-neurasthenia since June, 1907. Traumatic neurasthenia is more frequently met with in men than in women, and this is due to a large extent to the fact that the former are more liable to be accidentally injured in their occupations. At the same time, this difference in the character of the work of the two sexes does not altogether account for the prevalence of this semi-hysterical condition in males, for it has been noted that in a general catastrophe affecting a number of people the men will suffer in a greater proportion than the women. It seems also to be a fact that while working men after injuries are especially liable to suffer from hystero-neurasthenia, men engaged in professional or mercantile occupations are more prone to be attacked by simple neurasthenia.

When an injury is severe the nervous symptoms may be manifested immediately—by excitement, insomnia, nightmare, headache, tremors, emotional disturbance, and digestive troubles; in short, by what might be called acute neurasthenia. In individuals with stable nervous systems recovery takes place in a few days; in others of neurotic temperament, after perhaps a period of temporary improvement, the nervous manifestations return with greater or less intensity. When the traumatism has been slight, the victim of the accident may experience few symptoms of depression immediately after it, perhaps only vague pains and some weakness of the legs and slight insomnia—nothing to prevent him continuing his occupation. At the end, however, of a few days or weeks, or perhaps months, progressively or rapidly the symptoms characteristic of a traumatic neurosis appear, and a state of invalidism becomes more or less established.

The period of time extending between the receipt of the accident and the development of the neurosis has been termed by Charcot the "period of meditation." According to certain German authors referred to by Guion [4] this period may be prolonged for years; instances are given by these writers and by Guion where hysterical paralyses have developed in soldiers who had received wounds in the Franco-German war at periods varying from 2½ to 15 years after these injuries. Such deliberation in the appearance of traumatic injuries is almost incredible. In my experience the interval between the accident and the onset of the neurosis depending on it is seldom prolonged over two to three months. But, as Guion observes: "If during the long period which separates the traumatism from the hysterical explosion no other incident intervenes which may be invoked as the originator of the affection, then it is only natural to incriminate the traumatism."

From a medico-legal point of view a delay of even a month or two is of moment. For example, an individual meets with a more or less grave accident and receives an indemnity proportionate to the duration of his incapacity and returns to work. Subsequently, however, a traumatic hysteria assails him. This new and more serious trouble is only another effect of the accident, but in the present state of the law he is entitled to no further compensation, though he may be disabled for months or even possibly life. Railway and other companies in their own interests are therefore wise in seeking to settle claims made against them for damages as soon as possible. Finally, an individual under treatment for some disabling traumatic lesion may gradually become neurasthenic, and neither he nor his medical man recognises the nervous weakness until he attempts to resume work.

A traumatism may be followed by a pure neurasthenia or hysteria or by a hystero-neurasthenia; in the latter case the more precocious nervous manifestations are, as a rule, neurasthenic. When the individual is not destined to remain neurasthenic it may be a month or two before the earliest signs of hysteria appear, its advent being sometimes announced by a major or minor hysterical fit, the latter more commonly, the victim having what he calls "a fainty attack." On inquiry such a seizure will probably turn out to be not syncope, but a crisis characterised by palpitation, rushing sensations in the head, oppression of breathing, constriction of the throat, tremor, and emotional disturbance.

As stated previously, a traumatic neurosis most frequently takes the form of a hystero-neurasthenia. In this disorder the signs peculiar to each affection may be distinguished.

Neurasthenia, whether it occurs alone or in association with hysteria, betrays itself by its characteristic cranial discomfort, sensations of pressure or emptiness, or other abnormal feelings, heavy pain in the occiput or various parts of the cranium, aggravated by physical or mental effort, pain in the back, especially over the lower vertebræ and sacrum; often also a feeling of stiffness which retards free movements; and insomnia. There may be a difficulty in falling asleep, or sleep may more or less readily set in, but pass off in an hour or two, leaving the individual a prey to insufferable restlessness and fidgetiness, aggravated by tinglings in the limbs; there may also be any or all of the following: vertigo, tinnitus, and neuro-muscular asthenia, asthenopia, sexual weakness, circulatory disturbance, increased frequency or irregularity of the pulse, palpitation, spurious angina, vaso-motor irritability, atonic dyspepsia often associated with flatulence and constipation. The mental troubles are many and marked: on the emotional side there are sadness, weariness, and pessimism; repugnance to effort, abnormal irritability, defective control of temper, tendency to weep on slight provocation, timidity. On the intellectual side, lessened power of attention, defective memory and will power. The patient or his friends will say that since the accident he is an altered man. He has become inert, morose, and ill-tempered.

The objective symptoms, if there are any, are few and obscure. In a marked case the subject looks dejected and stupid; he stoops, and his gait and movements are sluggish; his speech slow and halting. The pupils may be dilated, and in very rare cases unequal; this condition was present in one only of my cases. The pulse may be quick, and often it is too readily accelerated. There is in some instances slight unsteadiness on standing with closed eyes. In others there is an abnormal tendency to flushing and sweating.

The emotional depression and the intellectual asthenia and the failure of will power tend to lead the neurasthenic to be possessed with doubts and fears. But the phobias of traumatic neurasthenia rarely reach the intensity of those found in congenital neurasthenia or of those common in hereditary degeneration. Moreover, the emotional depression renders neurasthenics liable to auto-suggestion; hence it is that hysteria so frequently complicates the disorder, and particularly in its traumatic form; for the working-man who is disabled is without any resources of distraction in himself, and frequent interviews with lawyers and medical men lead him to dwell on his injuries and symptoms.

Pure traumatic neurasthenia, as Oppenheim asserted, differs in some degree from the disease in its ordinary form. The victims of the disorder, even when educated, are not scribblers; they do not bring written descriptions of their troubles; unlike the ordinary sufferer from nervous exhaustion they do not chatter about their ailments. This taciturnity is embarrassing to the examiner, since leading questions have to be avoided. The patient is also easily annoyed and seems to look on the medical man with suspicion, even when he has been sent to him by his own

[4] Les Agents Provocateurs de l'Hystérie.

solicitor. He often, too, is worried by intellectual asthenia and emotional weakness, rather than by the indigestion, palpitation, and the other physical troubles of ordinary neurasthenia.

When I was a student neurasthenia was not recognised, and hospital patients who exhibited no signs of organic disease or of some familiar nervous disorder were usually set down as malingerers. With increased knowledge we now take a more humane and rational view of these cases, but as our diagnosis of pure neurasthenia largely depends on the statements of the subject under examination and not on objective signs, we have to guard against deception. In forming an opinion as to the veracity of an individual we are guided by the consistency of his statements, whether the description he gives of his troubles harmonises with the general features of neurasthenia; the clinical signs of this affection are remarkably uniform, and the truthfulness of a litigant may be tested by suggesting improbable symptoms. In doubtful cases more than one examination should be made and the reports of the different interviews compared. Some allowance, however, should be made for a little exaggeration, for, as Dubois observes when discussing the nature of neurasthenia, "around a nucleus of real fatigue there is a coating of imagination." The individual who goes to bed dominated by the idea of sleeplessness will remain awake. The man who thinks he can only walk a certain distance will not do much more. The idea of impotence increases the disability.

To the ignorant and prejudiced employer it seems incredible that a workman should be able to hang about the streets and not be fit to resume his occupation; but the fear of returning to work may be very real. We recognise the occasional presence of phobias, which may prevent an otherwise strong and capable man from following his occupation. Take this instance. A gentleman who had been a keen man of business, after a spell of overwork is attacked with anxiety neurosis—he dreads to go out alone and to go to business, but he eats and sleeps well, and with a friend can spend hours at a skating rink. Such a condition is unaccountable, but its reality is accepted because there can be no motive for deception. In the case of the working man claiming compensation there may be an inducement for simulation, but such a possibility should not provoke a hasty judgment. It is only just, to recall that in neurasthenia, owing to the abnormal introspectiveness which is one of its characteristics, there is a tendency to the unintentional exaggeration of symptoms, and, moreover, as I have stated, there is a liability to the development of phobias—to the generation of the "anxiety neurosis," the subjects of the disorder frequently asserting that they have "lost their nerve," that they have a terror of scaffolds, ladders, machinery, and of noise and bustle. With timidity there is usually infirmity of purpose, arising from failure of will power, as there is intellectual as well as physical weakness. Aches and pains are often associated with the muscular and mental asthenia, and these will be aggravated by effort.

As to simulation, I have only met with two malingerers in five years. Dr. Collie, in the report before referred to, found only 31 malingerers in 2658 official examinations of cases of diseases and accident. Taking traumatic neurosis only, Bouveret states: "I think complete simulation is very rare and constitutes only a very small exception. Exaggeration is more frequent than simulation." Oppenheim is of opinion that malingerers only occur in the proportion of 4 per cent. Strümpell, Schultz, and others are of Bouveret's opinion.

In hystero-neurasthenia the association of hysteria with neurasthenia not only leads to a modification of some of its symptoms, but to the interposition of others. To the insomnia of neurasthenia are added the nightmare and terrifying dreams of hysteria—the defects of memory become more pronounced. Neuralgic headache takes the place of duller pains and cranial discomfort, and similar acute pains are likely to be experienced in other parts. Associated with these symptoms are objective signs of great moment—the somatic stigmata of hysteria. I will refer to a few of them only. Fine tremor of the closed eyelids and perhaps of the hands, the former very constant. Modifications in the sensibility of the skin, even when partial, are very significant, as in analgesia or hypæsthesia of a part of the forehead or of the back of the forearm. Electro-anæsthesia is particularly common also—the interrupted current, applied over certain areas, causing no appearance of discomfort, but over others giving rise to expressions of pain. Concentric restriction of the visual fields. Modifications of the fields for colour vision; the field for blue reduced, and inside that for red. Asthenopia, amblyopia, defective perception of the size of objects—macropsia and micropsia; a victim of traumatic hysteria I recently examined mistook with one eye a sixpenny bit for a five-shilling piece. Defective senses of taste and smell. As regards the latter, the fifth nerve is in some cases involved as well as the olfactory, for I have found in these instances that strong ammonia held under one nostril has given rise to no evidence of discomfort, while under the other it has excited exclamations of pain. Defective reflex of the soft palate, exaggeration of the knee-jerks, spurious or genuine ankle clonus, with absence of the plantar reflex. Moreover, there is often a history of terrifying dreams, of failure of memory, occasionally presenting peculiar features. In one of my cases sudden loss of memory caused the subject of the accident frequently to lose his way when out in the streets. There may also be much talking and starting in sleep, and evidence of minor hysterical attacks—the so-called "half-faints."

Dr. Larat has recently[5] described a new, and in his opinion a pathognomonic, sign of traumatic neurosis in a peculiar electro-muscular reaction in which the contraction excited by the positive pole equals or exceeds that by the negative pole, A.C.C. = K.C.C. or A.C.C. > K.C.C., the current used = 10 milliampères. I have not repeated his experiments.

It might be asserted that the subject of a hystero-neurasthenia was hysterical before he met with an accident, and it is possible, but hardly likely, as the victims of this disorder are generally men.

Bernheim and his school, represented by Dr. P. Blum and Dr. Amselle,[6] deny the existence of interparoxysmal hysteria with its numerous stigmata. They hold that these stigmata are not peculiar to hysteria, that they can exist without any other nervous manifestations, and that they are produced by auto-suggestion, either because the subject amplifies organic sensations due to associated disorders or to suggestion acquired through medical examinations or in some other way. Further, they state that the psychical stigmata do not exist—that the mental state of the hysterical is in no way characteristic. They would limit the term hysteria to the paroxysmal attack—the crisis—its ancient signification; such attacks, they hold, do not constitute a disease but a morbid psycho-dynamic reaction. The unduly excitable persons liable to this reaction they term "hysterisable."

Babinski[7] adopts similar views, but would make susceptibility to suggestion the characteristic of hysteria. Dr. Pierre Janet, in his admirable description of the hysterical stigmata, supports the views of the Salpêtrière School.[8]

My experience, extending over many years, convinces me of the existence of normal hysteria and of its stigmata. In searching for these stigmata I have exercised the greatest care to avoid doing or saying anything which might give rise to suggestion. In most instances, too, the subjects examined by me for the hysterical stigmata had not been subjected to a similar mode of investigation before. Tremor of the closed eyelids has often suggested to me the probability of the existence of hysteria; the sensibility of the skin has then been tested by pricking. The eyes being still closed, it is well to begin with the left side of the forehead or the back of the left forearm, and then, nothing being said, to test in a similar way the corresponding parts on the opposite side, and note the expression of the patient, for his demeanour is usually sufficient to indicate to what extent the prick is felt or occasions discomfort. A pretty strong faradic current applied to one part may excite a cry of pain, while over the corresponding area on the other side it gives rise to no such demonstration.

I have analysed the cases of traumatic neuroses which I have seen in my consulting-room during the last five years. I

[5] La Presse Médicale, Dec. 8th, 1909.

[8] Les Névroses, par le Dr. Pierre Janet, 1910.

select these, because at home I have had the appliances necessary for thorough examination.

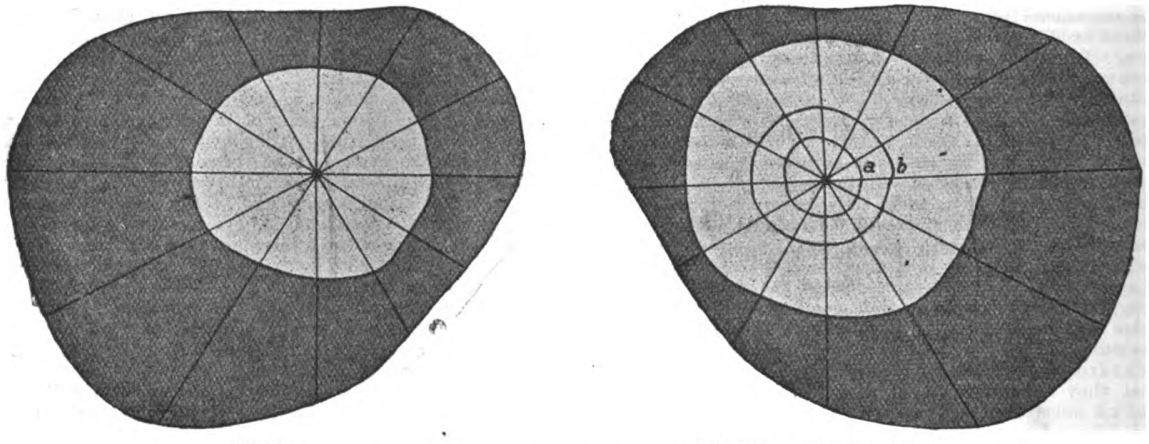
I find that the cases of traumatic neuroses are 40 in number; 23 of these are cases of hystero-neurasthenia, 13 of neurasthenia, and 4 of hysteria. 22 of the 23 traumatic hystero-neurasthenia cases were labouring men. Six of the 13 neurasthenia were persons of a better class injured in railway accidents. Of the 4 hysterical cases, 1 was a boy, another a girl, and the 2 others young men. In this return I have not included 2 cases of epilepsy and hystero-neurasthenia caused by blows on the head, nor 1 case of tabes and neurasthenia set down to a fall but probably due to other causes.

As to prognosis, cases of traumatic neurasthenia and mild hystero-neurasthenia, as is generally recognised, manifest a disposition to recover when they obtain compensation or damages, but the more severe hystero-neurasthenic cases do not exhibit the same tendency. I know cases where the disorder has continued from one to three years, and another, a case of traumatic neurasthenia, which lasted ten years. Oppenheim, in 33 cases of hystero-neurasthenia, met with 6 cases only of improvement, and Hodges 12 cases of recovery in 21. Bouveret states "that all observers are unanimous in affirming the gravity" of this disease. Vibert considers that the prognosis is grave when there is great mental depression, anxiety, tendency to weep, loss of memory, confusion of ideas, and profound change of character, accompanied by loss of strength and emaciation. According to the same author, the general development of the cerebral symptoms after some weeks' delay is another unfavourable sign. It is evident, therefore, that in the severer forms of traumatic neurosis, positive and unguarded opinions are to be avoided.

Analysis of the Remaining Cases of Hystero-neurasthenia—22

Tremor of closed eyelid	19
Generalised tremor	6
Defective sensibility of the skin sometimes limited to one-half of the forehead or the back of the forearm	20
Defective sensibility of the mucous membrane of the tongue, cheeks, or conjunctivæ	20
Electro-anæsthesia (but this test was omitted in some instances)	15
Defective sense of taste and smell (articles used, syrup and bisulphide of carbon)	16
Strong ammonia under a nostril not noted	4
Restriction of the visual fields (in one instance the vision was central only)	22
Achromatopsia	10
Asthenopia	6
Diplopia	3
Macropsia	1
Deafness	3
Knee-jerks exaggerated and plantar reflexes absent	18
Ankle clonus	4
Some unsteadiness, standing with closed eyes. (The less valuable psychical stigmata were present in many instances)	7
Very positive defects of memory	5
Tendency to sleeplessness	19
Terrifying dreams	14
Talking and starting in sleep	6

The significance of the somatic stigmata—the defects of sensibility—is increased by the fact that they are either limited to one and the same side or more marked on one side. I recently examined a man with traumatic hystero-neurasthenia in whom there was general and complete anæsthesia; no evidence of pain was manifested on thrusting a needle through the tongue nor on the application of faradic and galvanic currents, intense enough to cause tetanic contraction of the muscles.



Left field. Right field. *a*, field for blue. *b*, field for red.

(Inserted by permission of the Editor of the Liverpool Medico-Chirurgical Journal.)

I can only give particulars of one typical case of hystero-neurasthenia. I have analysed the symptoms presented by my other cases of this disorder with the view more particularly of indicating the frequency with which objective symptoms were met with, rather than to denote the comparative prevalence of the various hysterical stigmata.

A man, aged 28 years, was, while writing, struck on the head by a falling shutter and rendered unconscious for some hours. I saw him 13 months after. He had never returned to work, as he complained of general weakness, depression of spirits, loss of energy, defective memory, and tendency to sleeplessness. I found left hemianæsthesia and electro-anæsthesia, loss of sense of smell (bisulphide of carbon not being recognised held beneath left nostril; strong ammonia also in the same position caused no discomfort). Loss of taste for syrup on left side of tip of tongue, much restriction of the visual fields, inversion of the fields for red and blue (see charts) absence of palate reflex, ankle clonus, and plantar reflexes absent. He was liable to certain fits; they commenced with palpitation, a rushing sensation in the head and noise in the ears; he struggled and lost consciousness for some minutes. On coming out of an attack he clenched his fists, stiffened his legs, and arched his back

Liverpool.

DESMOID TUMOURS.

BY RUTHERFORD MORISON, M.B. EDIN., F.R.C.S. ENG. & EDIN.,
PROFESSOR OF SURGERY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE;
AND
HAMILTON DRUMMOND, M.B., B.S. DURH.,
SURGICAL REGISTRAR, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

IT is well recognised that fibrous tissue tumours, known as fibromata, may arise from any structure in the body where connective tissue is to be found, those arising from the fibrous tissue of the uterus affording perhaps examples *par excellence*. The term "desmoid," derived from the Greek δέσμος, and signifying something that has the characteristics of a ligament, is applied to such a tumour when occurring in the muscles or muscular fasciæ of the abdominal wall and

possessing certain clinical characteristics apart from fibromata occurring in other parts of the body. As several of these interesting tumours have come under our notice, a record of them is certainly justifiable, for not only are they uncommon, but, as the cases show, early recognition and free removal of such tumours may be the only means of preventing a fatal termination.

Of the seven cases that have occurred during the last few years, two are dead from the disease, one cannot be found, and the remaining four are well. One of these, however, underwent a second operation for recurrence of the growth seven months after the tumour was first removed. The separate case notes show that of the cases ending fatally one had a history of four operations, three of them being for recurrence of the disease, which eventually involved the hollow viscera in the abdominal cavity.

A striking feature mentioned in the literature is that nearly all of these growths occurred in women who had borne children and who not infrequently gave a history of difficult labour or of injury to the abdominal wall. Both Bidwell [1] and Harvey Stone [2] report cases in which the tumour was first noticed after the onset of pregnancy, and one of our patients (Case 1) noticed a swelling when she was six months pregnant. All the women had borne children, and one, indeed, twins, but nothing in their histories pointed to difficult labours, though a special attempt to establish this fact was not made.

The tumours are never tender on palpation, except in the later stages, when the peritoneum is involved. They have no movement further than that communicated by the abdominal wall on respiration. They do not disappear—on the contrary, indeed, they sometimes become more apparent—when the patient raises the head and shoulders, so rendering the abdominal muscles tense. These two latter signs are common to all tumours of the abdominal wall. As these growths increase in size they tend to do so in the plane of least resistance, and if arising from within the rectus sheath, whether from the sheath or from the muscle itself, the tumour spreads longitudinally upwards and downwards, and will not until a late stage advance laterally and perforate the sheath of the muscle. When occurring in the oblique muscles they give rise to sausage-shaped tumours which lie obliquely or transversely.

Although desmoid tumours have such well-marked clinical features that when these are known mistakes can scarcely be made, it is noteworthy that one was diagnosed and sent up as an enlarged gall-bladder containing many calculi, as the tumour lay in the upper part of the right rectus muscle; while in a second case a diagnosis of multiple sub-peritoneal fibroids of the uterus was made, the tumour, a large one in this case, occupying the lower part of the right rectus muscle. In a third case a diagnosis of appendix abscess had been made, and in a fourth so many differences of opinion arose as to the nature and the proper treatment of the growth after consultation in a London hospital that the patient decided to come to Newcastle for the operation.

It must be remembered, however, that although the majority of cases occur in women they may be found in men. Our cases showed six women and one man. The growths must be distinguished from tumours originating within the peritoneal cavity, and adherent to the belly wall, and from those that have their origin primarily in the abdominal wall. Of these latter the most commonly met with is the gumma or deep-seated abscess.

Without heeding the clinical features a desmoid may be mistaken for an abdominal tumour arising from any of the hollow viscera, depending upon the site and shape of the tumour. For instance, if the tumour is rounded and situated over the upper half of the right rectus muscle a diagnosis of pyloric growth may be made. Of the tumours having their origin within the peritoneal cavity, and sometimes closely simulating desmoids, a chronically inflamed appendix which invades the region of, and is adherent to, the abdominal wall, forming a pancake-like tumour, is most commonly met with. A large desmoid undergoing myxomatous change may exhibit precisely the same features when situated in the right iliac fossa. These growths may exist for a long time before they show any great increase in size. In one case the tumour had been known to exist for three years before it began to grow seriously. They are in some instances first noticed during pregnancy, the increasing vascularity of the abdominal wall in pregnancy appearing to stimulate the tumour to more rapid growth, and thus bringing it for the first time to the notice of the patient.

On section, to the naked eye, these tumours show whorls of fibrous tissue similar to uterine fibroids, though the growing edge is often soft and pearl-coloured, and can be seen pushing its way through the strands of muscle. The microscopical appearance, if the section be taken from the growing edge of the tumour, will show spindle cells with but little fibrous tissue. At the centre, however, where the blood-supply is less active, fibrous tissue will be in excess. The changes undergone are mucoid, showing cysts, myxomatous change, fibrosis, and lastly, but to be distinguished from the above instances of degeneration, malignant change. This was the termination of Case 5, and it is owing to the possibility of such change occurring that immediately a tumour in the abdominal wall, however small, is discovered, exploration and microscopical examination should follow without delay.

Conclusions.—There are certain tumours—desmoids—originating in the abdominal wall, chiefly in the upper half of the rectus muscle, but also in connexion with the other muscles, which are of considerable clinical importance.

They are likely to be mistaken for growths *in* the abdomen, unless the possibility of their occurrence is remembered.

Their association with pregnancy is so frequent as to constitute more than a coincidence. Possibly traumatism, by muscle stretching or tearing, is of etiological significance.

A firm, but not tender, sausage-shaped tumour, possessed of some mobility, across, but not in the direction of the fibres of the relaxed muscle with which it appears to be associated, becoming fixed when that muscle is made tense, and occurring in a woman recently pregnant, is a desmoid tumour.

The treatment is to excise the growth at once, along with a free margin of the surrounding structures, including the peritoneum underlying it.

CASE 1.—A woman, aged 19 years, married; one child, aged 6 months. Admitted complaining of a swelling below the lower ribs on the left side on Sept. 4th, 1902. The swelling was smooth, very hard, and appeared to be connected with the upper part of the left rectus muscle and to be attached to the ribs. (The patient had noticed the swelling for three years.) Operation Sept. 4th by Dr. A. Parkin (who was then Mr. Morison's house surgeon). An incision was made over the mass, which was incised and found to be a growth in the rectus muscle and adherent to the ribs. The whole mass with the affected portion of the muscle and ribs was excised. The skin incision was closed with silkworm gut. The divided muscles were not sutured. The patient left hospital on the 12th healed. Pathological report: "Spindle-celled sarcoma."

In December, 1901, a nodule was discovered in the scar and it was considered to be a recurrence. In May, 1902, she complained of pain and a mass could be felt in the margin of the scar near the ribs. She was not readmitted till March 15th, 1903, with a definite tumour in the upper third of the scar, conical in shape, about 1½ inches by 1 inch, not attached to the ribs. Operation (Mr. Morison) on March 27th. A vertical elliptical incision, including the old scar, was made into the peritoneal cavity in the middle line below the ensiform cartilage. The peritoneum just over the left lobe of the liver was invaded by the growth. The upper surface of the left lobe of the liver was roughened by adhesions, but there was no visible growth in the liver itself. The costal cartilages of the seventh, eighth, and ninth ribs were divided on the outer side, and the portion of abdominal and thoracic wall between this and the mid-line, including the tumour, was excised down to the middle of the upper half of the rectus muscle. In removing the attached portion of diaphragm an opening was made into the pleura and air was sucked in. The pericardium with the heart beating forcibly in it was exposed at the bottom of the wound. A piece of indiarubber sheeting packed down with gauze was used to occlude the hole into the pleura and the skin only was sutured over the gap. It was not possible on account of the size of the opening to make a more effective closure of it. The patient bore this formidable operation well and recovered with very little shock. The portion removed included an ellipse of scarred skin 3½ inches by 1½ and portions of three costal cartilages, the longest being 4 inches. The growth appeared to have extended towards the peritoneum between two ribs and projected against it by three knob-like processes. The peritoneum covering these was roughened but did not appear to be invaded by the growth, which had a definite capsule, except at one part where it was quite soft and brain-like and had burst. The remainder of the growth presented the appearance of a fibroma. Pathologist's report: "Spindle-celled sarcoma." The patient left hospital on July 10th.

Nine months later (April 8th, 1904) she was readmitted because she had noticed something coming back and it had caused her some pain. On examination there was a mass of growth occupying the remaining portion of the upper half of the left rectus muscle for about three inches and below the old scar, which was healthy. It was of interest to note how firm the abdominal wall had become from cicatricial tissue at the site of the extensive removal of all of its structures except the skin, for there was no hernia, and it felt strong. Operation on April 12th. The abdomen was opened in the middle line to the right of the tumour, which was then seen to be adherent by its deep surface to the

[1] West London Medical Journal, 1906, vol. xi.
[2] Annals of Surgery, vol. clxxxviii.

liver and to the omentum. After separation of the adhesions and gauze packing the growth was widely excised through a crucial incision. The abdominal wall was repaired as well as seemed possible by deep thick catgut sutures.

Four months later (August, 1904) the patient reported herself. She looked well and strong and there was no sign of recurrence. She was readmitted three months later (Nov. 7th) greatly changed, as she was now thin and looked anæmic and complained of pain coming on after food. On palpating the abdomen a deep mass was felt in the neighbourhood of the umbilicus adherent to the abdominal wall. Operation on Nov. 15th. On opening the abdomen the mass was found to be adherent to the abdominal wall and invading the stomach and duodenum. An attempt was made to remove it, and during this the growth was opened and a large mass of soft broken-down material came away. The lesser sac was now found to be filled by growth which presented through the gastro-hepatic omentum and the attempt to do a complete operation was abandoned. The visceral openings and the abdominal wall were closed by suture, and severe shock followed the operation.

The pathologist's report of the tumour was "spindle-celled sarcoma." The patient gradually recovered from shock, but died 13 days after the operation soon after the formation of a duodenal fistula. Post-mortem examination showed that all the visible growth had been removed, but that the lesser sac was full of it. There were no secondary deposits in the lungs or in any of the other viscera. The opening in the duodenum was in its first part on the upper surface just beyond the pylorus and was due to leakage from the part sutured.

CASE 2.—A married woman, aged 36 years; had had two children aged 1 and 8 years. Twelve months ago the patient accidentally discovered a lump in her right side. It was quite painless, and except for a slight pricking sensation caused her no inconvenience of any kind. The tumour had grown in size very little since it was first noticed, and on examination a large easily palpable tumour was found in the region of the gall-bladder and in connexion with the right rectus muscle. It was not tender and could be picked up and held between the finger and thumb. On Feb. 22nd, 1905, a vertical incision was made over the tumour, which was widely excised. The whole of the rectus muscle surrounding it and a portion of the peritoneum about the middle of the posterior surface of the tumour where it was adherent were removed. The abdomen was closed in four layers. The tumour on section was hard and firm like a fibroma. The pathologist's report was: "Dense fibroma containing spindle cells." December, 1908: Well; no recurrence. March, 1910: Well.

CASE 3.—A married woman, aged 28 years; had had two children, 4 and 2½ years. Admitted to hospital July 23rd, 1906. Patient was well up to four years ago, when she noticed that something was wrong with her left side. She made this observation shortly after her confinement. Six months later she noticed a definite lump in the same situation which had gradually got larger and was now of about the size of a hen's egg. Examination showed a hard nodular tumour in the abdominal wall above Poupart's ligament and above the left pubic spine. As her abdomen was a lax one the tumour could be lifted up between a finger and thumb. Operation on July 24th. Oblique incision over the tumour 4 inches in length. The tumour was in the rectus muscle. It was removed with the adjoining and surrounding muscle and the abdominal wall was closed in layers. Examination of the tumour showed all the characters of a fibroma. It sprang from the sheath of the rectus muscle. Pathologist's report: "Fibrifying spindle-celled sarcoma." This patient cannot be found, having left the district.

CASE 4.—A married woman, aged 35 years. The patient had three children, the last born two years ago, when she had twins. Five weeks ago she noticed a tumour 1 inch below the ribs and towards the right side; quite painless. On examination there was a small hard rounded tumour in the right rectus muscle just below the umbilicus. The tumour could still be felt when the abdominal muscles were made tense. A longitudinal incision was made over the swelling and a portion of the rectus muscle and its sheath, including the growth, was removed along with the peritoneum, which was adherent behind. The muscles were drawn together by a series of strong catgut sutures. On section the growth cut and looked like a fibroma invading the rectus muscle and its sheath. The pathological report was "Fibrifying spindle-celled sarcoma invading voluntary muscle."

CASE 5.—A man, aged 33 years, was admitted to hospital on Feb. 6th, 1907. He looked ill and had lost weight. He complained of loss of appetite and night pain in the right side of the abdomen, which had a swelling in it. On examination, there was a hard, cake-like mass in the right iliac fossa, which at one point showed an area of softening. On the 9th an oblique incision was made over the tumour and the muscles divided. They were infiltrated with a fibrous deposit, and in parts showed soft débris-like growth. The peritoneal cavity was not opened. The microscopical report was that the "structure is that of myxomatous degeneration, probably sarcomatous." Patient developed a faecal fistula on March 9th, and left hospital a few days afterwards in very poor general condition. Several months later he was traced to the Western Infirmary, Glasgow, where he died.

CASE 6.—A married woman, aged 25 years, was admitted to hospital on March 9th, 1908, complaining of a lump in the right side of five months' duration. She had had two children; the first was a year old and the second eight weeks. The tumour was painless and had not increased in size. On examination, patient was a small, thin woman and had a hard tumour of the size of a hen's egg in the upper part of the right rectus muscle. It had a sharply defined inner and outer edge, but above and below ended indefinitely in the muscle. It had all the characters of a tumour in the abdominal wall. On March 10th the abdomen was opened in the middle line parallel to the tumour, and a transverse incision was made above and below the growth. All the structures of the abdominal wall around the tumour were removed down to the peritoneum which was left intact. The divided edges of the internal oblique and transversalis muscles were drawn over to and stitched to the linea alba, and the tendon of the external oblique was sutured over them. The tumour, which measured 4 inches by 3 inches and was 1 inch thick and invading the rectus muscle, was closely incorporated with its anterior sheath. On section the tumour looked like a fibroid of the uterus and showed definite whorls of fibrous tissue, with small mucoid cysts in its interior. Patient left the hospital well. On Oct. 17th of the same year she returned with a recurrence, stating that she had remained well for four months after the operation, when she again observed the tumour, which was quite painless as before. Her general condition was good. At the lower aspect of the incision in the rectus muscle there was a hard small mass of growth. On Oct. 20th, 1908, by a U-shaped flap he abdomen was opened and the whole of the portion of the rectus muscle containing the growth was widely removed. The omentum was brought up to fill the gap in the peritoneum and the muscles were brought together as well as possible, being sutured with silk. She made an uninterrupted recovery and left hospital well and healed. On March 17th, 1910, she was seen again. She was in excellent health and there was no recurrence and no weakness in the scar, and she could do her housework well. On both occasions the pathologist's report was that the "tumour was a fibro-sarcoma."

CASE 7.—A female, aged 30 years. Had had two children, the youngest three years ago. About two years before admission she noticed a lump of the size of a walnut below and to the right of the umbilicus. Recently the swelling had increased in size rapidly. It had always been quite painless. It was first noticed 12 months after the last child was born. The tumour was hard and not tender, and was about 2½ inches long by 1½ inches across its middle. It followed the line of the rectus muscle and had all the characteristics of an abdominal wall tumour. On Oct. 31st, 1908, a V-shaped incision was made over the tumour. The lower part of the rectus muscle below the tumour was divided across, the deep epigastric artery being ligatured and divided. The peritoneal cavity was opened in the middle line, and the middle third of the rectus muscle, including the aponeurosis and peritoneum, were removed. The abdominal wall was repaired by suturing the peritoneum separately, and the linea alba was brought to the cut edges of the transversalis and oblique muscles. On section the tumour was lozenge-shaped, hard, and fibrous. The pathological report was: "Fibrifying spindle-celled sarcoma with myxomatous change."

NOTES OF SOME CASES TREATED BY VACCINES OF UNKNOWN ORGANISMS.

BY E. C. BOUSFIELD, D.P.H. CAMB. & LOND.,
DIRECTOR, CAMBERWELL RESEARCH LABORATORIES; BACTERIOLOGIST, METROPOLITAN BOROUGHS OF CAMBERWELL AND HACKNEY.

NOT the least merit of the vaccine treatment of disease is the fact that it necessarily involves the determination of the actual cause of the ailment from which a given patient is suffering, and so differs essentially from those methods which depend upon the treatment not of diseases but of symptoms. This determination of the specific cause is at once the source of its strength and the index of its limitations.

Attempts are too often made, it is to be feared, to employ vaccines on the supposition that if they do no good they can, at any rate, do little or no harm. This is no doubt very largely true, especially since in some cases there is what may be called a symbiotic infection, in which more than one factor is concerned, as, for example, pustular acne, in which the staphylococcic infection is secondary to that of the bacillus which determines by its presence the formation of the comedones, and the pustules may be cured without relieving the acne itself in the least. Or it may happen, and often does, that the apparent cause is an organism which does not lend itself to classification, either because of its unusual form, or because the condition of the patient is such as not to allow time for the purpose. Of this class are three of the four following cases.

CASE 1.—*Pleurisy following measles.*—The patient was a boy, aged 12 years, the son of a medical man. He had had an attack of measles followed by whooping-cough, and upon this combination there had supervened a severe attack of broncho-pneumonia, in the course of which he had developed pleurisy over the surface of both lungs. There were loud friction-sounds to be heard at many points, but no fluid could at any time be detected anywhere. As the patient's condition was extremely grave, I was asked to do my best to prepare a vaccine for him. The only material available was the sputum, which was scanty and slightly rusty. The mouth was cleansed as far as possible, and a small quantity of sputum was secured. This was thoroughly washed in sterile salt solution, several times successively, and a small fragment from the last washing was rubbed thoroughly on blood serum. A very scanty growth was secured in one tube, and this sufficed to make two doses of vaccine, the organism being a coccus of irregular size, from a minute dot to a cell of about half the size of a torula. The first dose lowered the temperature within 24 hours nearly to normal—it had previously ranged from 101° to 103·5° F.—and the second dose, two days after the first, still further improved matters. The good effect, however, was only temporary, and it was necessary to repeat the process of preparation. This time five doses were obtained, and four of these were administered with continuous improvement, but the fifth was mislaid, and after five days the symptoms recrudesced. Fortunately the fifth dose was at last recovered and sufficed to bring the temperature to normal and keep it

there, and the boy made a good recovery. His younger brother, who was taken ill at the same time, succumbed to the initial disease before I was called in.

CASE 2. *Malignant endocarditis, with phlebitis.*—I was summoned to Wantage to see, in conjunction with Mr. W. M. Woodhouse, a lady who had been ill for some weeks with high temperature and signs of general blood infection, including phlebitis—in both legs if I remember rightly—and evidence of vegetations in the form of a pronounced mitral murmur. I made several cultures, mixing the patient's blood with ordinary nutrient agar and sloping the tubes, as well as taking smears. The blood used for the cultures was withdrawn from the median basilic vein, under strict antiseptic precautions, and a scanty growth was obtained, though the whole of the tubes afforded sufficient for the provision of ten tubes of vaccine. The organism was apparently a simple staphylococcus, but would not grow on any other medium than blood-agar. When the vaccine reached Mr. Woodhouse the patient felt so much better that she refused to have it administered. About a month afterwards the symptoms reappeared, and the patient being in practically the same condition as before, I advised the use of the vaccine. The first dose reduced the temperature practically to normal, and only two more were administered, the patient's condition rapidly improving. After a few weeks many of the symptoms returned, but they were again removed by the use of the remainder of the vaccine, and I am informed by Mr. A. E. Cawston, into whose hands the case has passed, that all that is left is a small amount of blockage of the veins, which is also disappearing. No trace of the mitral murmur remains.

The next two cases are of pyrexia following delivery, but totally different in origin in the two cases.

CASE 3. *Puerperal toxæmia due to B. coli communis.*—The patient was an inmate of the British Lying-in Hospital, in whom severe pyrexia developed about the fifth day. She was a multipara. The material supplied to me consisted of a swab which had been charged in the uterine cavity. Having made the ordinary cultures, it occurred to me that the infection might be due to continuity of surface, and I washed the swab off in a tube of McConkey broth. There was a large and rapid growth of typical B. coli, and I prepared a vaccine of which three doses only were required to effect a cure, and the patient was discharged perfectly well about the fourteenth day.

CASE 4. *Puerperal toxæmia, due to an unidentified organism.*—I was asked by Dr. R. Thurston to see with him a woman who, after a normal confinement, had developed rigors, returning at intervals of from 12 to 16 hours, with concomitant high temperature, and followed by profuse sweating. I saw the patient about the eighth day and found the lochia somewhat purulent, but not particularly offensive, and the general condition fairly good. There was no sign of localised peritonitis nor any marked abdominal tenderness. By Dr. Thurston's wish I withdrew 10 c.c. of blood from the median basilic vein, but for my own satisfaction I had the vagina carefully cleansed and took a swab from the interior of the uterus. Cultures were made on the spot from both sources, but the blood coagulated so rapidly that there was much difficulty in utilising the whole amount taken. This may account for the fact that there was a growth of B. mesentericus in one tube, though all the others remained sterile. From the swab an abundant growth of a white staphylococcus was obtained, which grew freely on the ordinary media. From this a vaccine was prepared, but though the patient appeared to benefit at first, and the intervals between the rigors increased, this was only temporary. A second swab was taken and gave no better result. A third one, however, was taken coincidently with what Dr. Thurston described as a slight rush of pus. This gave on culture the same staphyloccocus as before, but in many times smaller numbers, and also a diphtheroid bacillus, familiar to me in troubles of long standing within the genito-urinary passages, to which, from the difficulty of subculturing it, I have given the name of B. fugax. A couple of doses of this were made, and the first one increased the interval to 48 hours, whilst the second put an end to the rigors altogether, and the patient improved steadily and satisfactorily, so that there was no need to use the other ten doses which were sent as soon as ready. I advised that one more should be administered, however, to make assurance doubly sure.

The case which follows is rather an example of scientific guessing than of diagnosis, but the gravity of the condition and the age of the patient lend it considerable interest.

CASE 5. *Cholecystitis in a gall-bladder full of gall-stones.*—I was summoned to Nottingham by Dr. W. T. Rowe to see a lady of 83 who had suddenly, after over-exertion, developed acute cholecystitis, and in whom Dr. Rowe had satisfied himself that the gall-bladder was full of calculi. In view of the age of the patient, and the great risk of an operation, I was led to consider the possible agent of infection, and as it seemed probable that B. coli was the organism concerned I took down with me a dose of 100 millions just prepared for another patient. After consultation this was administered, and marked improvement followed. Before my next visit I had prepared a "coli" vaccine from the patient's own fæces, and except for one day, when the symptoms seemed to return with full force for 24 hours, the improvement in the patient's condition was continuous, and she is now, having received five injections, after six weeks as well as ever, though, so far as can be judged, the calculi are still *in situ*. As the patient in this case happened to be my own mother it will be understood that the issue gave me special satisfaction.

In view of the favourable character of the results in the foregoing cases it seems desirable to draw attention to the fact that they were obtained under the best possible conditions—namely, in all cases, either by myself making the cultures directly at the bedside, or by the careful exclusion of possible contamination.

Medical men frequently ask how much blood is needed for the preparation of a vaccine. It cannot be too insistently stated that, for blood cultures at any rate, the latter must be made at the bedside, and incubated at the earliest possible moment. Drops of blood from fingers or ears are absolutely worthless either for examination for bacteria—except in anthrax—or for the preparation of vaccines, and most of all does this apply to blood sent in capillary or other tubes, in which the whole of the particulate matter is entangled in the clot, even if one could have the least confidence that any growth obtained or organism seen was actually present in the blood, and was not the result of accidental contamination. It is hardly too much to say that the presence of the "opsonist" is almost as necessary for the success of a blood-culture as that of the surgeon for the performance of an operation.

De Crespigny-park, Denmark Hill, S.E.

PRIMARY ACIDOSIS; RECOVERY.

BY SIDNEY BONTOR, M.D., M.S. DURH.,
SURGEON TO THE WEST HERTS HOSPITAL.

MUCH attention has been given lately to the production of "acidosis" by anæsthetics and as the terminal condition of such complaints as diabetes. The following case, which is probably the first recorded instance of recovery after a severe primary acid-intoxication in an adult, will therefore, I think, be of interest.

The patient, a widow, aged 68 years, has always enjoyed good health, although rather pale and not very robust. Except for an attack of acute nephritis in 1887 she has had no illness. She took an ordinary mixed diet, but has always been a small eater; she takes an occasional glass of wine, but has been practically an abstainer from alcoholic beverages for the last 20 years. She drinks an average of 2½ pints of fluid daily, and she leads a regular, healthy life. On Nov. 9th last year, until when she had been in her usual health, she remained some time in her garden and became exceedingly cold, so cold that in spite of her wrapping up with hot bottles in a warm room she was a very long time getting warm again. Headache came on during the evening and prevented her from sleeping during the night. On the next day the headache was worse and she felt sick but did not vomit; the bowels acted as usual. She got up at midday, but movement aggravated the feeling of sickness and the headache so that she was unable to do anything. This condition continued for the next three days, the headache quite incapacitating her. Her diet was very small in amount and consisted of fish and milk puddings with plenty of drinks.

On Nov. 13th I saw the patient for the first time. She was then feeling better, but still had headache rather severely. She appeared to be recovering from an intestinal toxæmia; the feeling of sickness had passed off, her temperature was 98° F., her bowels had acted each day after a small dose of saline in the morning, and her

urine was normal. (The urine had been examined on several occasions since her attack of nephritis 20 years ago and had always been normal.) During that day she had the same diet and felt better, sleeping pretty well. On the next day she felt still better in the morning and had some bacon for breakfast and some chicken at her midday meal. During the afternoon, however, the headache returned and gradually increased in severity, and she became drowsy but did not have continuous sleep. On the 15th the headache was "crushing" and she was quite drowsy and apathetic. On the 16th and 17th she was constantly sick and the bowels did not act; she could only take fluids. On the 18th she became slightly delirious, and was wandering all night. Her bowels acted well after a small dose of calomel; the urine was still normal. On the 20th she was practically unconscious, but could be roused occasionally; Dr. R. Hutchison kindly saw her with me, and he gave a very bad prognosis, expecting she would not survive many days. From then until Dec. 11th she never recovered consciousness, on some days being so deeply comatose that she would not respond to any stimulus, food placed in her mouth remaining unswallowed. For three days (Dec. 2nd to 5th) there was well-marked Cheyne-Stokes respiration. On those days she vomited several times, the vomit being very acid; she was not quite so deeply unconscious afterwards, and with much care about three pints of nourishment were able to be administered daily. On Dec. 10th she began to be less deeply unconscious, gradually improved, and made an uninterrupted recovery, being able to sit out of bed by the 20th and to go downstairs on Christmas Day, and now, a year afterwards, she feels as well as ever she did, except perhaps a little less vigorous.

The diagnosis of this case was difficult. It was evidently a toxæmia and appeared to rest between uræmia, an intestinal infection, and acidosis, but at first there was nothing to enable a differential diagnosis to be made. The urine, which was examined nearly every day, gave no definite reaction until Nov. 22nd—13 days from the onset of the condition. Then diacetic acid was found to be present and the condition was shown to be one of acid intoxication, and a line of treatment was framed to meet the condition. In order to keep up the store of glycogen the diet was entirely limited to carbohydrates, and with a view of neutralising as far as possible the acid condition bicarbonate of soda was introduced into the system as freely as possible. It was given in every feed and by slow introduction into the rectum, according to Murphy's plan, of continuous rectal infusion as long as the bowel would tolerate it, and afterwards by occasional enemata.

Bearing in mind the striking results obtained by Young and Williams, which have proved that acetonæmia varies with the amount of oxygen intake during anæsthetisation, oxygen was administered freely day and night, and one of the first recollections of the patient is the extremely refreshing sensation produced by its inhalation. Strychnine was commenced when the heart began to fail, and was kept up until recovery was assured; 1/60th grain was given every four hours at first, and subsequently twice a day. The administration of food was extremely difficult, and the patient's recovery must be largely attributed to the great care and patience exercised by her daughter and the nurse, 20 minutes frequently being required to adminster a few ounces of food.

The consideration of the etiology of this case is interesting. The exciting cause appears to have been the extreme cold experienced on Nov. 9th. This probably so interfered with the digestive processes that an intestinal toxæmia was induced; and subsequently, by their work in dealing with the resulting toxins, the liver cells were so damaged that they were incapable of performing their normal function of transforming the carbohydrates into glycogen. Moreover, as this particular patient has always been a very small eater, and is always pale and has a very small amount of adipose tissue, it is possible that her store of glycogen is always very small; and as extreme cold is one of the causes which produce loss of glycogen, it is probable that this store of glycogen became exhausted during the first few days of her illness. This view is supported by the fact that, after a temporary recovery, she became rapidly worse when acid-producing foods were introduced on Nov. 14th. The original toxæmia appeared to be passing off, but in consequence of the impaired action of the liver cells and the exhaustion of her store of glycogen, the fatty acids were not fully oxidised, and the organic acids, combining with the alkaline bases of the blood, reduced its alkalinity until the "acidosis" was produced.

The diacetic reaction disappeared from the urine on Dec. 9th and the urine has remained normal ever since. She is now taking her ordinary diet and leading her usual life.

Great Berkhamsted.

THE USE OF THE FARADIC CURRENT IN THE TREATMENT OF PERSISTENT APHONIA FOLLOWING LARYNGITIS; TWO CASES.

BY FRANCIS HERNAMAN-JOHNSON, M.D.,
CH.B. ABERD., R.N. (RETIRED),
HONORARY SURGEON AND RADIOGRAPHER, BISHOP AUCKLAND DISTRICT HOSPITAL, DURHAM; LATE SURGEON, ROYAL NAVAL HOSPITAL, PLYMOUTH.

IN setting forth the following cases, together with such brief comments as seem to me desirable, I have no wish to pose as a laryngologist. It is rather as one interested in the application of electricity in its simpler forms to the exigencies of everyday practice that I venture to hope what I have to say may prove of some value.

CASE 1. *Aphonia of 12 years' duration.*—The patient, a clerk, aged 38 years, in his early manhood had been what is popularly known as a "local preacher," and for years indulged in pulpit oratory of a vehement nature. On two or three occasions during this period he lost his voice for a few days, but it always returned with rest. At length, however, being upon one occasion, in the depths of winter, called to preach at a remote country chapel, he caught a severe cold and was confined to bed for a fortnight. Meanwhile his voice left him entirely, and to his alarm did not return with the subsidence of the bronchial symptoms. During the ensuing decade the patient submitted to a variety of treatments at the hands of various medical men—sprays, gargles, lozenges, internal paintings, external blisterings—in fact, ran the whole gamut of orthodox remedies many times over. All this was of no avail. Finally, at unqualified hands he underwent a four months' course of what, so far as I could gather from his description, must have been the galvanic or continuous current. The result was likewise *nil*. A laryngoscopic examination showed the vocal cords to be slightly thickened and pinkish in colour. On attempting phonation they failed to approximate fully, remaining separated by an elliptical opening—a state of affairs due to paresis of the internal tensor muscles. Judged by the long history, the case did not look very promising from the point of view of treatment. All I could tell the patient was that a course of electricity might be of benefit. He, however, demurred, saying that he had already undergone (and paid for) such a course. It was not until I convinced him by personal application that the form of current I purposed using differed from the one previously experienced that he consented to a fortnight's trial. Two weeks' mild external faradisation produced the following result. Aphonia was no longer absolute; true voice sounds could be produced at times, especially in the morning when the patient was fresh. With the laryngoscope an attempt to phonate was seen at first to be successful, the cords approximating fairly well; but the adductor muscles were not yet equal to sustained effort, and soon relaxed. A month's further treatment on these lines was carried out, with the addition of piano-aided exercises in producing and sustaining low notes. By the end of this time speech had become entirely vocal, except at such times as the patient was very fatigued, when a relapse occurred to the old whispered speech. It would be idle to say that his voice was perfect, or even pleasing, but at least he was now able to make himself heard across an ordinary room—a feat of which he had been incapable for nearly 12 years. Whether or not anything more could have been accomplished I am unable to say, as the patient's firm chose this particular time to remove him to another town. He called on me six months later, and his voice was then practically the same as when I last heard him.

CASE 2.—The patient, a school teacher, aged 22 years, a cousin of the man referred to above, came to me complaining of similar throat trouble; the aphonia, however, was not

absolute, speech in a hoarse, croaking voice being occasionally possible. There was no history of excessive strain, but one of repeated neglected "colds," with accompanying laryngitis. A gradual deterioration of the voice resulted from this neglect, and it finally became so bad that the girl was obliged to resign her position as a teacher. This occurred two years before I first saw her. A view of the larynx showed the vocal cords somewhat swollen and congested. Efforts to speak resulted in a fair degree of approximation, except that a small triangular space remained at the back of the glottis. The aphonia was therefore apparently as much due to catarrhal changes in the tension and vibration of the cords as to neuro-muscular defect. In addition to the laryngeal inflammation, there existed permanently swollen tonsils, congestion of the pharynx, and adenoids. The patient was quite unable to breathe through the nose. The question of treatment presented difficulties. The girl expected to be cured, as her relative had been, by the simple application of electricity. A consideration of the facts of the case made me not very hopeful as to the benefits to be derived from faradisation alone. I recommended preliminary removal of the tonsils, &c., but finally yielded to her importunities, and consented to try the effect of a fortnight's treatment. Some improvement certainly resulted, but it was not very striking. At the end of the agreed period I again urged surgical interference. This time the patient consented; a very thorough operation was performed, and, perhaps for the first time in her life, she was able to breathe fully through her nose. After about a week's time—that is to say, as soon as the irritation due to the surgical trauma had subsided—the voice began to improve, and continued to do so for some weeks. Two months after the operation the patient could speak vocally, but in rough, unpleasant tones. Tested by the piano for musical notes, she was unable to produce anything higher than an indifferent "middle C." I waited another six weeks, to see if any further spontaneous improvement would occur. As it did not, I decided to recommence faradic stimulation, with a view to improving the pitch and timbre of the voice. The results were most gratifying. In a short time the patient was able to manage "F," and later "A," but beyond this point no progress seemed possible. The patient's speaking voice is now of good volume and no more than slightly rasping. She has been able to obtain another post as teacher.

Remarks.—A study of the above cases, and of others of a similar nature which have come under my notice, has led me to form certain conclusions regarding the pathology and treatment of persistent post-catarrhal aphonia. Text-book accounts of chronic laryngitis and its accompanying disturbances of voice appear to me to err in regarding the disease as if it were on all fours with, say, a tracheitis. In other words, attention is concentrated on the mucous membrane to the neglect of other equally important structures. The larynx is primarily a mechanical device for the production of vocal sounds, and depends for its proper functioning even more upon the integrity of its muscles and nerves than upon the healthiness of their covering. In chronic catarrh of this organ the muscles become secondarily affected, and the delicate terminals of the motor nerves in all probability undergo an inflammatory degeneration. An acutely inflamed mucosa doubtless demands local sedative applications; and even when the trouble has become chronic, astringent sprays, paintings, &c., can often play an important part. But the tendency in many chronic cases is for the mucous engorgement to disappear to a great extent, whereas the damage to the neuro-muscular apparatus remains. Under such circumstances it is unreasonable to expect a cure by the ordinary means. On the other hand, improvement may be looked for from such measures of "natural therapy" as produce benefit in similar pathological conditions elsewhere—e.g., in that form of facial palsy which is the result of exposure to cold.

In treating paresis of laryngeal muscles by faradisation we are at a disadvantage as compared with the same conditions occurring in an arm or leg. We cannot single out the affected muscle or muscles for individual stimulation. This difficulty is not, however, insurmountable. The secret of success lies in the regular and persistent use of *mild currents*, which are not calculated to produce violent contractions of opposing healthy muscles. If carefully applied for a prolonged period this form of electricity exercises a selective action on the affected structures and eventually restores their tone.

Remarkable as are the results of faradism in suitable cases, we must not fall into the error of regarding it as a panacea for each and every form of catarrhal aphonia. Where the laryngoscope shows marked swelling and congestion of the cords the mucous membrane must be attacked vigorously on orthodox lines, and here again we are likely to meet with little success if the naso-pharynx is in an unhealthy condition. Nevertheless, even where the mucosa is the part most at fault, the judicious use of the interrupted current forms a valuable adjunct to routine treatment.

In conclusion, it is perhaps desirable to urge the necessity, in any given case, of making sure that the aphonia has really resulted from such simple causes as catarrh, overstrain, or a combination of both. Thoracic aneurysm, lesions of the central nervous system, malignant growths, the ulceration of syphilis or of tubercle—these must always be borne in mind as sinister possibilities, and to waste time in faradising a patient who subsequently dies from cancer or is cured by iodide of potassium is to run the risk of being dubbed—not undeservedly—a quack.

Bishop Auckland, Durham.

NOTES ON A CASE OF PHLEGMASIA ALBA DOLENS, FOLLOWED BY PULMONARY EMBOLISM AND INFARCTION OF THE LUNG; RECOVERY.

BY J. C. CURTIS, L.R.C.P. & S. EDIN.

THE patient, a married woman aged 28 years, a primipara, gave birth to an eight months' female child on May 16th. She resided in the country and was attended by a village nurse. She went on satisfactorily until May 21st when she developed phlegmasia alba dolens in the left leg. The whole limb was considerably swollen, the swelling extending as high as Poupart's ligament. No thrombosed vein could be detected in the thigh or leg. It was therefore apparent that the circulatory block was in the pelvis. The swollen limb measured 1 inch more than the sound one, and was accompanied by the usual pain. The temperature was 101° F., pulse 90, and respirations 30. The limb was treated by lightly applying cotton-wool, and the foot of the bed was slightly elevated on wooden blocks. The lochia were somewhat offensive, and so hot permanganate douches were given night and morning. The bowels were regulated by enemata. The patient progressed favourably. On the 26th the leg was much less painful and her temperature normal, but there was no appreciable diminution in the swelling. On the night of the 28th she was seized with violent pains in the left chest and shortness of breath. As her husband expressed it, "she had awful pains in her chest, and I expected her to die every minute."

When seen on the morning of the 29th the patient was in a very distressed condition. The respirations were 72; pulse 108, regular, but very feeble; and temperature 100°. The extremities were cold. She complained of intense pain over the epigastrium, precordia, and lower axilla. She was too ill for any detailed examination, but an impaired note was found over the lower part of the axilla, and the breath sounds over this area were badly transmitted; no friction sound was heard. A soft systolic murmur could be heard over the pulmonary area and the second sound was accentuated. She suffered from retching and some vomiting, and the giving of the smallest amounts of liquid nourishment caused great pain over the precordia and lower axilla. As her stomach was dilated this was attributed to pressure on the diaphragm interfering with cardiac and respiratory movements. Hot water bottles were applied to the feet and hot applications to the chest. She was given iced milk and soda-water with brandy in small quantities at frequent intervals. She was also given the following mixture every four hours: bismuth carbonate, 10 grains; aromatic spirit of ammonia, 15 minims; compound tincture of cardamoms, 10 minims; mucilage, q.s., and water to 1 ounce. On the following day (30th) the vomiting had ceased. The respirations were 66, pulse 102, and temperature 101°. She still had considerable pain over the lower axilla, and a marked friction sound could be heard over this area, and it

was noticed that the swelling in the left leg had considerably diminished; it was much softer and free from pain. The pulmonary systolic murmur could still be heard, although not so marked.

On June 3rd there was a considerably impaired note over the lower half of the upper lobe, and the whole of the lower lobe and axilla, with marked tubular breathing, bronchophony, and pectoriloquy. The pleuritic rub was still very much in evidence. The temperature was 99°, respiratory rate 60, and pulse 96, regular, and of medium tension. The pulmonary sounds were now clear. The patient was very cheerful. She had a slight dry cough, but no sanguineous expectoration. She complained of a slight pain in the axilla when she took a deep breath. She was taking an abudance of fluid nourishment. On the 9th the respiratory rate had dropped to 30. There was good air entry at the base, but dulness persisted over the axilla, the lower half of the upper lobe, and the upper half of the lower lobe; and over these areas there were still tubular breathing, bronchophony, and pectoriloquy. There was still an occasional dry cough but no expectoration. The temperature was normal. The left leg had resumed its normal size. The lung symptoms gradually cleared up, and on the 18th the pulse was 72, regular, and strong. The respiratory rate was 24, and there was good air entry over the whole lung. She still had a little pain over the lower axilla when taking a deep breath. She was up and about on the 19th, and on August 5th was quite well.

The chief points in the case were: (1) the large area of lung involved; (2) the almost simultaneous disappearance of the œdema in the leg, coincident with the lung lesion; (3) the small amount of pyrexia, pointing to an aseptic condition of the lung lesion; (4) the high respiratory rate, due to the large amount of lung tissue thrown out of action; and (5) total absence of any sanguineous expectoration, and practically no cough. I should add that the urine was examined and nothing abnormal was found. The case occurred in the practice of Dr. W. W. Anderson of Tring, and I am indebted to him for permission to publish it.

Mumbles, near Swansea.

THE INFLUENCE OF QUININE AND MORPHIA UPON PHAGOCYTOSIS.

BY H. LYON SMITH, M.D. DURH.,
FORMERLY REID SCHOLAR AND FOULIS RESEARCH SCHOLAR.

IT may be accepted that experiments *in vitro* fail to reproduce the complicated processes which occur in the living subject, and that deductions drawn from them are unsound unless other evidence can be adduced in support. In spite of this discouraging premise, I have ventured to make a series of researches to ascertain, if possible, the truth of the oft-repeated statement that quinine, like alcohol in excess, inhibits phagocytosis, and is therefore contra-indicated in all septic conditions.

The opsonic index was taken as a basis for the work, with the additional factor of a solution of quinine and morphia. By way of control, to avoid the possibility of error in the index being affected by chemotaxis, in each group one index was taken with a volume of salt solution in place of the quinine and morphia, but it did not appear that the mere mechanical effect of diluting the ordinary constituents of an opsonic content influenced the result of the count. The very soluble acid hydrochloride of quinine was selected because it is much less irritating than the sulphate and contains 8 per cent. more quinine. Morphia hydrochloride, 1/8 grain, was added to each 10 grains of the quinine salt, because in practice I have found the combination more efficacious than either alkaloid used alone.

It was roughly calculated that a 10-grain dose given to a 10-stone person, if entirely absorbed, would represent in the blood a proportion of 1 in 7500, on Waller's estimate that the ratio between the weight of the blood and the weight of an individual is about 1 to 15. The influence of this solution (1/7500, equivalent to a 10 grain dose) upon the phagocytosis of different kinds of pathogenic organisms (e.g., streptococci, staphylococci, pneumococci, B. coli, B. influenzæ, B. pseudodiphtheriæ, and B. tuberculosis) was contrasted with stronger and weaker solutions to ascertain the effect of varying doses.

The details of a typical experiment were as follows:—

A. One volume each of (1) washed human blood corpuscles; (2) human serum; (3) fresh emulsion of living B. coli; and (4) 1 7500 solution of quinine and morphia. These were thoroughly mixed in a Wright's pipette, sealed, and incubated in an opsoniser at 37° C. for 15 minutes. Films were then made, stained, and counted.

In B of the same group No. 4 contained 1/30,000 solution of quinine and morphia, equivalent to a 2½-grain dose.

In C No. 4 was replaced by a volume of sodium chloride solution, 0·85 per cent.

In D No. 4 was omitted, as in an ordinary test for an opsonic index.

To avoid the risk of bias, or as Sir Almroth Wright put it, "to be careful lest one should find what one wished to find," the different slides were "shuffled" by an independent person and thus counted without knowledge of which was which. Dr. W. E. de Korté was kind enough to help me in this matter and to corroborate the results in some cases by making independent counts.

In this B. coli experiment the phagocytic counts were A = 428, B = 321, C = 164, and D = 261, 100 polynuclear leucocytes being counted in each case. The addition of quinine and morphia had increased the phagocytosis in this case by 64 per cent. for the 10-grain dose and 23 per cent. for the 2½-grain dose.

I was only able to complete 11 sets of experiments, and in the majority of them there was an increased phagocytosis, always most marked with the 10-grain dose solution.

Summary of Results showing Increase of Phagocytosis.

	Per cent.		Per cent.
1. Streptococci	30	8. A pseudo-diphtheria bacillus	20
2. B. coli	64	9. B. coli (a second strain)	30
4. Pneumococci...	80	10. Pneumococci (a second strain)	30
6. Streptococci (another strain)...	90	11. B. coli (a third strain)...	250
7. B. influenzæ	20		

It appears that, instead of inhibiting phagocytosis with the above micro-organisms, the addition of quinine and morphia, in what may be considered the "ideal" dose, greatly increased it. Smaller doses in all the groups were less effective, and one important fact was clearly demonstrated—namely, that very large doses, 30 and 40 grains, instead of increasing, actually diminished phagocytosis, sometimes to the extent of over 50 per cent. This latter observation makes me think that the statement that quinine is contra-indicated in bacterial invasions is based upon experiments in which too strong solutions have been used, doses which would undoubtedly have a most depressing or even poisonous effect upon patients.

It will be noted that groups Nos. 3 and 5 have been left out of the list of experiments which showed increases. In No. 3 tubercle bacilli were used and the result was a diminished phagocytosis. In No. 5 staphylococci formed the bacterial emulsion and a 10-grain dose solution diminished the count by 50 per cent., whereas a one-grain dose solution gave a very slight increase. It takes a quinine solution of 1/400 to inhibit the growth of certain bacteria (staphylococci), and we may safely assume that any bactericidal effect is quite out of court in the therapeutical doses.

I would submit that the stimulus to phagocytosis in the foregoing test-tube cases was due to the quinine and morphia acting as an opsonin to certain microbes. If the result had been simply due to stimulation of the leucocytes, groups Nos. 3 and 5 would not have differed in such marked fashion from the others.

In the initial stages of a bacterial invasion, and particularly in cases of appendicitis, acute colitis, puerperal septicæmia, cellulitis, erysipelas, and influenza, the prompt administration of quinine in the ideal dose (which seems to be about 1 grain to each stone of the patient's weight) appears likely to strengthen the natural first line of defence. It is at this period, when the invaders are comparatively few in numbers, that a remedy which will quickly increase phagocytic power is of the greatest service and may possibly abort the attack. Even if it fails to achieve complete success it postpones the immediate danger and affords time to bring into play more exact methods of serum or vaccine treatment.

Mansfield-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF OPTIC ATROPHY FOLLOWING SUPRAORBITAL INJURY.

BY A. GASCOIGNE WILDEY, M.R.C.S. ENG.,
FLEET SURGEON, ROYAL NAVY.

AN A.B., aged 26 years, while cycling on August 1st, 1909, was thrown by the skidding of his machine and fell upon his head. He was slightly concussed, and received a small contused wound over the right orbit. Upon recovering consciousness he complained of headache and of complete loss of vision of the right eye. The accident occurred at 4 P.M. He was seen by a medical officer of the Royal Naval Barracks, Devonport, at 10 P.M. The wound was found to be superficial. There was some slight œdema of the upper lid. No injury to the eye could be detected. There were no obvious signs of fracture of the skull. Amaurosis of the right eye was complete, perception of light being absent. Both pupils reacted to light. There was no proptosis nor increased tension of the globe. On the following morning an examination by ophthalmoscope was made, but nothing abnormal found. The right pupil did not react in attempts to accommodate. Examination of the area of distribution of the supraorbital nerve showed no loss of sensation. On August 9th there was some return of perception of light, and on the 12th the patient stated that he could distinguish the outline of a person in a good light at about 15 feet. He could dimly make out the largest letters of Snellen's types at 1 metre.

Atrophic changes in the right disc were observed on August 14th, the temporal side of the disc being distinctly pale. Perception of light was absent on the nasal side of the fundus. A perimeter chart made on the 20th showed that such vision as existed was limited to a very small central area confined to the nasal side in the 40° circle. Within this area there was a central scotoma. Colour vision was limited to an exceedingly small central spot on the nasal side within the 20° circle. Subsequent examinations proved that a rapid increase of atrophic changes was taking place. The right disc was generally paler and distinctly white on the temporal side. On Sept. 17th the area of perception of light was limited to a small irregular patch in the lower and nasal portion of the 20° circle.

In this case it is probable there was a fracture of the sphenoid through the optic foramen with lesion of the optic nerve. Here, somewhat fortunately, loss of vision was noticed immediately the patient recovered consciousness; it might easily have passed unnoticed for a considerable time, since the dressings of the supraorbital wound covered the eye, and there was some œdema of the lid. Hence these cases, formerly called "supraorbital" amauroses in the belief that the loss of vision was in sympathy with a lesion of the supraorbital nerve, are of considerable interest medico-legally, and the possibility of a fracture through the optic foramen with subsequent atrophic changes in the optic nerve should be considered in all cases of supraorbital injury.

A PRACTICAL APPLICATION OF THE SYMPTOM-COMPLEX IN RUPTURED ABDOMINAL HYDATID CYST.

BY A. H. TEBBUTT, M.B. SYDNEY,
AND
D. A. WELSH, M.A., M.D. EDIN.

A SYMPTOM-COMPLEX in ruptured abdominal hydatid cyst was recently described by Barling and Welsh[1] as consisting of eosinophil leucocytosis, peritonitis with effusion, and urticaria, the last, however, not always being observed. This association of phenomena had an interesting application in the diagnosis of a recent case.

A woman, 42 years old, had suffered since girlhood from recurring "bilious attacks." Two weeks before admission she had one of these attacks, and after vomiting noticed that her abdomen was swollen. The swelling had persisted ever since its somewhat sudden onset. No itching or rash was noticed by the patient.

On admission on August 3rd, 1910, she was wasted, sick, and listless, with slight intermittent pyrexia, and a rapid, soft pulse. The abdomen was greatly distended with fluid and the superficial veins were dilated. Fluid was withdrawn from the abdomen on August 6th for diagnostic purposes. It appeared straw-coloured and deposited a brownish granular sediment after some hours. In the sediment the endothelial cells were scanty. A few cells of doubtful identity were found, but no hooklets nor scolices. The great majority of the cells were leucocytes, and there was a remarkable accumulation of eosinophil forms. The differential count (240 counted) showed: eosinophils, 81·6 per cent.; lymphocytes, 13·0 per cent.; neutrophils, 5·0 per cent.; and basophils, 0·4 per cent. A blood examination on the 8th revealed a high degree of eosinophilia. The leucocytes altogether numbered 25,000 per c.mm., and on counting 300 cells the leucocytes were found to be made up as follows: eosinophils, 29·0 per cent.; neutrophils, 54·0 per cent.; lymphocytes, &c., 16·6 per cent.; and basophils, 0·4 per cent. There was, therefore, a well-marked eosinophil leucocytosis, together with a slight neutrophil leucocytosis. The precipitin test was negative, but the hydatid fluid employed had never given a satisfactory reaction, and in these circumstances the absence of the reaction could not be regarded as significant.

Operation showed abundance of free fluid and lymph, together with several daughter-cysts, in the peritoneal sac. On the under surface of the liver there was found a large hydatid cyst which had ruptured far back, and enormous numbers of daughter-cysts and fluid were contained within it.

The interest of the case lies in the association of a ruptured hydatid cyst of the liver with the appearance of free fluid in the peritoneal sac and with a high proportion of eosinophil cells in the blood and in the peritoneal fluid. Though no urticarial eruption was noticed by the patient these phenomena otherwise correspond with the symptom-complex, and illustrate the diagnostic importance of this association, as the symptoms otherwise pointed to malignant disease.

We are indebted to Dr. Mills and Dr. Abbott for their kind permission to make use of the clinical notes of the case.

Sydney.

NOTES ON TWO CASES OF ECZEMA EXUDANS TREATED SUCCESSFULLY WITH HIGH-FREQUENCY CURRENTS AND KEROL.

BY G. M. LOWE, M.D. EDIN., F.R.C.P. EDIN.

IN common with many others I have found mild currents (70 milliampères) of great service in the treatment of chronic diseases of the skin, especially those where the constitutional condition of the patient indicates an irritable state of the trophic nerves, a condition so frequently met with in middle-aged women.

In the following cases, although great benefit followed the above application, their cure was not complete until I used a preparation sold under the name of lana kerol, which is described by the makers (Quibell Bros., Limited) as an oxidised di-phenyl compound, which is comparatively insoluble, and for this reason very much less toxic than phenol; the active di-phenyl compound is made miscible with water by means of a special soap, and this causes it to form a perfect emulsion with water. Its bactericidal qualities are highly vouched for by such observers as Dr. D. Sommerville and Mr. W. C. C. Pakes, and Professor R. T. Hewlett.

CASE 1.—The patient was a lady, aged 50 years, who had been suffering from eczema exudans for 20 years; the disease came on soon after the birth of her only son. She is a tall, spare, active woman, worn down with the constant irritation of the eruption which covered the face and almost every part of the body. She had, of course, used every remedy that had been suggested to her, and was unwilling to try anything further. I found high-frequency currents and the effleuve very efficacious in relieving the irritation of the skin and in improving the general health. She was very careful to follow out the prescribed diet, and for a time a cure seemed

probable; but as from time to time there was a return of the eruption in the axillæ and groin, I prescribed lana kerol 1 in 300 parts as a lotion, the diseased skin to be thoroughly washed with it every night and morning, the flexures to be dressed with unguentum rusci co., and the erythematous surfaces to be dusted with boric acid powder. The result was a complete cure, and there has been no return in 12 months.

CASE 2.—The patient was a lady, aged 60 years, very thin, but strong and energetic, who had been subject to eczema for over ten years. The skin is thin, dry, and irritable; the eruption affects chiefly the neck and scalp, as well as the axillæ, back, and flexures of the thighs. Change of air, high-frequency currents, and calamine applications effected a temporary cure last year, but the complaint returned in March, 1910. Her home is in an exposed locality on a clay soil. As she could not come to me for treatment I sent a capable nurse with instructions to cleanse every part of the skin night and morning with the kerol solution (1 in 300) and then apply the unguentum rusci co. and boric acid powder as required. In three weeks my nurse returned reporting an absolute cure.

ROYAL SOCIETY OF MEDICINE.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Presidential Address.

THE first meeting of the session of this section was held on Oct. 18th, when the President, Professor A. R. CUSHNY, delivered his presidential address, entitled "A Plea for the Study of Therapeutics." He traced the changes of clinical sentiment, from the optimistic faith in the few available remedies current in the early nineteenth century, to the sceptical attitude towards drugs of the modern physician. In the mid-nineteenth century, when, under the influence of pathological anatomy, medicine had become pessimistic and treatment almost wholly expectant, the new school of pharmacology perforce abandoned the hospital wards for the laboratory. The time had come for applying to the practice of the wards the principles learned in the laboratory, and for insisting on accurate quantitative records, hitherto so conspicuously lacking in clinical literature. Professor R. Stockman's work on salicylates was a model of such accurate clinical investigation. Ergot might be cited as a drug for the clinical investigation of which laboratory work had now furnished the data. The President described, and illustrated by charts and records, his joint investigation, with Dr. James Mackenzie, of the action of drugs affecting the circulation, and chiefly of the cardiac tonics. The future course of this investigation was indicated and the increasing necessity for work of this type emphasised. The President outlined the changes in organisation necessary to bring into their proper relation research and instruction in pharmacology and in therapeutics. The hour being late the meeting adjourned without discussion of the address.

MEDICAL SECTION.

Multiple Cartilaginous Exostoses.

A MEETING of this section was held on Oct. 25th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. A. M. GOSSAGE and Mr. E. ROCK CARLING communicated a paper on Multiple Cartilaginous Exostoses. According to the authors the occurrence of this condition was rare, but was probably more frequent than was usually supposed, since the condition often gave rise to no discomfort. The tumours arose from the intermediate cartilage and were generally first noticed during the first two years of life, but might be present at birth. They were very variable in size and number and usually required no treatment, but might cause discomfort by pressure on adjacent structures, when they should be removed. They had been supposed to be a consequence of rheumatism, syphilis, or rickets, but there was no real evidence in favour of any of those views. There was evidently some inherent abnormality of the intermediate cartilage which caused it to develop in an unusual manner, and that abnormality was very frequently hereditary. Evidence was adduced to show that the abnormality of the intermediate cartilage resulted not only in the production of bony tumours but also in alterations in the size and length of the bones. The inheritance seemed to obey Mendel's law, an affected person transmitting the abnormality to about half his children by a normal mate, there being no evidence of increased or diminished intensity during successive generations. Males were, however, affected about twice as often as females, but normal women in affected families not infrequently transmitted the abnormality to some of their children, while it was probable that normal males never did so. There were a considerable number of sporadic cases in which no history of any similar complaint amongst the relatives could be obtained, but it was possible that some of those did not arise *de novo* but were really hereditary, the transmission having taken place through one or more normal females. The records of 51 families were dealt with, of which 30 were reported fairly fully. In those 30 families, taking only the later generations of the offspring of affected individuals, 121 were abnormal and 130 normal. Cases from two previously unrecorded families were included and described.

Professor BATESON (Cambridge) said that the cases approached the Mendelian characteristics, but he did not think in the strict sense of the term that they should be included under Mendel's law.

After Dr. S. R. WELLS had spoken, Mr. CARLING and Dr. GOSSAGE replied.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.

A MEETING of this section was held on Oct. 28th, Dr. E. CAUTLEY, the President, being in the chair.

Mr. W. HAMPSON exhibited (for Dr. ERIC PRITCHARD) a case of Achondroplasia in a girl aged 5 years. The skiagrams showed defective ossification of the epiphyses of the long bones with overgrowth of the cartilages. The patellæ were either absent or rudimentary.

Dr. T. R. WHIPHAM showed a Heart presenting atresia of the pulmonary artery, patent foramen ovale, and deficient interventricular septum. The right side was hypertrophied and the left carotid artery arose from the innominate artery. The patient, aged 1 year and 9 months, was shown on May 27th and presented marked cyanosis and clubbing of the digits. There was a polycythæmia of 12,740,000 red corpuscles per cubic millimetre and a hæmoglobin value of 200 per cent. The only murmur heard was a faint systolic bruit over the pulmonary area.

Dr. D. WOOD showed an infant, aged 5 weeks, with a Cleft in the Hard and Soft Palate, the cleft being occupied by new growths which were of an uncertain nature.

Dr. F. LANGMEAD showed a case of Scleroderma Neonatorum with Myositis Fibrosa in an infant aged 8 months. The face, trunk, and limbs were all affected, and the temperature showed a daily rise to from 99° to 100° F.

Mr. J. P. LOCKHART MUMMERY exhibited a girl, aged 5½ years, with a Tumour on the Posterior Aspect of the Left Rectus Abdominis Muscle, which had almost disappeared under iodide of potassium. There were no other signs or history of congenital syphilis.

Mr. DOUGLAS DREW showed a boy, aged 10 years, with Injury to the Right Brachial Plexus as the result of being crushed by a van-wheel. The arm presented a paralysis of the Duchenne-Erb type, with weakness of the extensors of the wrist and slight anæsthesia over the shoulder. The paralysed muscles showed reaction of degeneration and had not regained power.

Mr. Drew also exhibited a boy, aged 5 years, in whom a fall had caused a Separation of the Lower Epiphysis of the Humerus, with displacement inwards.

Dr. J. D. ROLLESTON showed charts and photographs of a case of Gangrene of the Leg following Diphtheria in a boy aged 13 years. No antitoxin had been given, and when seen on the seventeenth day the right leg below the knee was cold and anæsthetic. Dilatation of the heart and a temporary discolouration in both legs ensued. On the thirtieth day there was commencing gangrene of the left leg and obliteration of the pulse in the popliteal artery. Amputation through

the knee-joint was subsequently performed and recovery was uneventful.

Dr. ROLLESTON also showed charts and photographs of Concurrent Scarlet Fever and Chicken-pox. The patient, a boy, aged 8 years, had been exposed to chicken-pox three weeks previously, and was admitted with a typical scarlet fever throat and rash. On the following day the varicella eruption appeared. Subsequently there was a profuse desquamation which confirmed the diagnosis of scarlet fever. The child made a good recovery.

Dr. G. A. SUTHERLAND exhibited a female, aged 3½ years, the subject of Recurrent Tetany. The attacks began seven months previously after prolonged indigestion and abdominal distension. The tetany was typical, facial irritability being marked at times and laryngeal stridor occasionally present. There were no signs of active rickets.

Dr. J. B. MOLONY and Dr. H. D. ROLLESTON showed a case of Idiopathic Hypertrophic Dilatation of the Colon, with skiagrams. The patient, a male, aged 3 years, was weaned at the sixteenth month, and then had bouts of constipation with progressive abdominal distension. The bowels were very obstinate, and in spite of a ravenous appetite the child became emaciated. Bilious vomiting occurred from time to time, and peristalsis along the course of the colon was observed, but was unaccompanied by pain. Skiagrams taken after a bismuth meal showed an enormously distended bowel in the region of the ascending colon and a normal transverse portion, while a tube containing a soft wire passed into the anus indicated a distended rectum extending up to the diaphragm.

Mr. C. T. DENT exhibited a child, aged 4 months, with "Congenital Elephantiasis" of the Right Arm, a condition allied to cystic hygroma. There was also a superficial nævus or condition of cavernous angioma. The bones appeared normal in a skiagram but were probably longer than in the corresponding limb.

Dr. LEONARD GUTHRIE exhibited a case of Congenital Insufficiency of the Soft Palate in a girl aged 9 years. Regurgitation of fluids through the nose occurred during the first five years of life but not afterwards. The speech was marked by rhinolalia. The soft palate was normal in appearance but motionless on phonation and on stimulation. The condition was thought to be one of muscular insufficiency rather than of submucous cleft palate.

Mr. P. G. LEE sent the report of a case of Deficiency in the Interventricular Septum and Patent Ductus Arteriosus in a child aged 7 years.

The cases were discussed by the PRESIDENT, Dr. PORTER PARKINSON, Mr. DREW, Dr. LANGMEAD, Dr. PARKES WEBER, Mr. MUMMERY, and Dr. WHIPHAM.

MEDICO-LEGAL SOCIETY.

Presidential Address.

AT a meeting of this society held on Oct. 25th,

Sir JOHN TWEEDY, the President, delivered an address upon the Influence of Social and Legal Restrictions on the Practice of Medicine. The history of medicine, he said, including surgery, furnished many instances of the deterrent effects which various regulations and restrictions, risks and penalties, had had upon the practice of medicine. In some cases the restrictions and penalties had been imposed by external authority, in others they had been imposed by real or by quasi-medical authority, and in others they had had their origin in the peculiar civil and social conditions of the time. Besides these there had been esoteric influences at work, due to the difficulties and dangers inherent to practice at a time when knowledge was imperfect and the methods of diagnosis and treatment defective and uncertain. Egyptian medicine and its practitioners had been famous in very early times. In the fourth book of Homer's Odyssey we were told, "In Egypt each man is a physician skilled beyond all mankind." Herodotus, writing in the fifth century B.C., stated that medicine was practised in Egypt on a plan of separation, each physician treating a single disorder and no more. And so the country swarmed with medical practitioners, some undertaking to cure diseases of the eye, others of the head, others again of the teeth, others of the intestines, and some diseases which are not local. This elaborate specialisation might in one sense be regarded as evidence of a high degree of proficiency, but it was also evidence of a somewhat restricted training, inasmuch as the practice of most of the specialties was hereditary and each person studied only one specialty. Medical knowledge and skill had attained their high level under the fostering care of an hereditary priesthood, but after a certain stage of development was reached the sacerdotal influence proved hostile to all experiment and progress. Egyptian physicians were obliged to treat their patients according to the rules laid down in those parts of the sacred books of Hermes which dealt with the body and its diseases. The death of a patient was a capital crime if it was found that he had been treated in another way. It was true that deviations from, and approved additions to, the sacred prescriptions were occasionally made, and Aristotle observed that even in Egypt a physician was allowed after the fourth day to alter the treatment prescribed by authority, while if he did this before he did it at his peril. In striking contrast to the rigid regulation of Egypt it might be noted that in ancient Greece there seemed to have been no liability for malpraxis, while in regard to ancient Rome, Pliny complained that there was no law to punish the ignorance of physicians, a physician being the only person who could kill a man with impunity. From the recently discovered code of laws promulgated by Hammurabi about 2300 B.C. it had been learnt that liability for malpraxis was severe in ancient Babylon. If a medical man treated a person of position for a severe wound with a lancet of bronze and caused the patient to die, or opened an abscess of the eye with a bronze lancet and caused the loss of the eye, the surgeon's hands were to be cut off. With such a penalty in prospect it was surprising that there had been anyone willing to undertake the treatment of any surgical case whatever. The retaliatory mode of settling a surgeon's bill in the time of Hammurabi was, however, scarcely less drastic than that which obtained in Europe 3000 years later. In the plague which visited Europe towards the end of the sixth century one of the victims was Austregild, Duchess of Burgundy. Prior to her death she accused the physicians of administering potions intended to kill her, and she entreated the King to avenge the crime. After the obsequies had been performed the King discharged the oath which he had freely given, and satisfied the posthumous desire of the princess by slaying her surgeons according to the old Teutonic law. The laws of the Visigoths, for example, laid down that if a physician blundered in blood-letting when the patient was of noble birth so as to debilitate him he should pay a fine of heavy damages. If the patient died the surgeon was delivered over to the nearest relatives of the deceased, who thereafter became the absolute arbiters of his life and death. In the early part of the fourteenth century Pope John XXII. having accused his physician-barber of seeking to bring about his death by sorcery and poison had him flayed alive. The same Pope burnt at Florence another of his physicians as a sorcerer, upon the denunciation of a professional colleague, and yet the Pope himself was a believer in astrology, sorcery, and witchcraft. About the same time John, the blind King of Bohemia, who was killed at the battle of Crecy wildly but heroically fighting at the head of his knights, caused the French surgeon who had failed to cure his eye to be sewn up in a sack and thrown into the river Oder. The legal, social, and civil penalties to which surgeons in the Middle Ages were exposed accounted for much of the timidity and reserve of mediæval surgery. Other causes peculiar to the state of surgery at that time were the ignorance of anatomy, the dread of hæmorrhage and the imperfect means of arresting it, and not least, perhaps, the contempt with which surgery was regarded by the clerical physicians of that time. "O God," exclaimed the famous Italian surgeon, Lanfranc, towards the end of the thirteenth century, "why is it that there is now so much difference between a physician and a surgeon, except that physicians have abandoned manual operations to laymen? *They* say it is because they disdain to work with their hands, but *I* believe it is because they do not know how to perform operations." Leopold Duke of Austria, the captor of Richard Coeur de Lion, had had his leg fractured by the kick of a horse. The limb mortified and amputation was necessary, but no surgeon could be found willing to undertake the operation. At length, unable to bear his pain, the operation was performed by the Duke himself holding an axe to the limb while his

chamberlain struck the axe three blows with a mallet. But the Duke's sufferings continued and the inflammation spread to the body. The bishops seeing him in such a state of misery and suffering admitted him to the communion of the faithful, "after which," said Roger of Wendover, "he expired in dreadful agony."

The scarcity of surgeons and their reluctance to undertake the treatment of serious cases in distinguished persons was exemplified in the case of Mathias Corvin, King of Hungary, who having been wounded in the arm in a battle with the Turks in 1468 caused it to be known throughout Europe that he would liberally reward anyone who would cure him. Many months passed before a surgeon offered his services. At length Hans of Dockenberg, a surgeon living at Strasburg, went to Bohemia, cured the king, and returned to his home rich in rewards and reputation. The dread of undertaking the treatment of serious cases was almost an obsession with mediæval surgeons. Guy of Chauliac, who flourished in the fourteenth century, and was the greatest European surgeon from the time of Hippocrates to his own day, warned surgeons against undertaking what he designated "bad cures"—*malas curas*. In Guy's case the warning was mainly based upon considerations of the personal risks to which the surgeon exposed himself. It was noteworthy, however, that the writer of the Hippocratic treatise "De Arte" also advised physicians not to undertake desperate cases, but it was not the dread of personal consequence that influenced him. It was the observance of an enlightened and logical principle. "Medicine," he said, "is the delivering of sick persons from their sufferings, and the diminishing the violence of diseases, and not the undertaking of treatment of those who are overcome by sickness, because the medical art here is of no avail." He argued that medicine was an art, and when a person was afflicted with a malady beyond the power of the therapeutical resources of medicine one could not expect art to triumph. The consideration of the difference in attitude between the Hippocratist and the surgeons of the Middle Ages suggested the inference that wherever and whenever the medical profession and medical practice had been most highly organised, the penalties for failure and ill-success had been most humane; and wherever they had been less organised the penalties had been harsh, vindictive, and often inhuman. In the more highly organised state of medicine practitioners had been better educated and more skilful, bolder and yet more cautious and circumspect, and therefore more trusted. When the organisation had been imperfect the number of educated physicians and surgeons had been fewer, while quacks and charlatans had been most numerous and most unconscionable. Brunus, writing in the middle of the thirteenth century, stated that the majority of those who practised surgery in his time were uneducated, rustic, and stupid. Many of the surgical practitioners from the fourteenth to the sixteenth century belonged to a special class called Operators. These practitioners performed operations which were either forbidden to the clerical physicians or were abandoned by the Masters of Surgery, such as hernia and cataract; in fact, all the operations the consequences of which might be grave or fatal. Not a few of the operators belonged to the category which Guy of Chauliac, for good reasons, designated "coureurs." They had no fixed abode, but led a wandering life, travelling from town to town, and from country to country, in search of patients and of cases requiring operation. Pierre Franco, who lived in the middle of the sixteenth century, was a distinguished and skilled member of this class of operators. He complained more than once of the contempt which the physicians of the day had for the work of surgery and for the operator. And he observed, not without a touch of acerbity, that if a patient died in the hands of the physician, the physician was always excused in some degree, and so also with a surgeon who did not practise operations; "but when what *we* undertake does not always succeed as happily as we could wish, we are called *murderers* and *executioners*, and have often to take to our heels."

Upon one other aspect of the subject Sir John Tweedy touched in a few words in conclusion. In ancient Greece and in ancient Rome slaves were employed to do menial tasks and much of the industrial work. There were, however, some slaves of a higher order who were skilled in branches of learning or of art, and who acted as secretaries (like Cicero's beloved Tiro) or copyists, librarians, pædagogi or tutors of children. Some had considerable knowledge of medicine and surgery. While these gifts generally ensured good and even kindly treatment, they often lessened the chances of gaining complete freedom. The slave was often manumitted, but he still remained in a position of subordination to his master, and could seldom return to his native land if he so desired. Sir John Tweedy trusted that his remarks had been sufficient to establish his thesis—viz., that the restrictions and restraints placed upon the practice of medicine in former times, and the penalties incurred under liabilities for malpraxis, had done much to hamper the practice of surgery and to check the progress of medicine. A glance at the existing law relating to the medical profession sufficed to show how far they had travelled on the path of reason and humanity. In this respect at least it might be said that they had passed from contract to status. No medical man now made a contract guaranteeing a cure. Chief Justice Tindal laid it down that "everyone who enters a learned profession undertakes to bring to the exercise of it a reasonable degree of care and skill. He does not undertake if he is an attorney that at all events you shall win your case; nor does a surgeon undertake that he will perform a cure, nor does he undertake to use the highest possible degree of skill, but he undertakes to bring a fair, reasonable, and competent degree of skill." So also with respect to penalties. Chief Baron Pollock in the case of R *v* Crick remarked: "It would be most fatal to the whole efficiency of the medical profession if no one could administer medicine without a halter round his neck." Similarly Mr. Justice Park: "It would be a dreadful thing if a man were to be called in question criminally whenever he happened to miscarry in his practice."

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases, &c.—Development of Multiple Growths.—Pyloric Stenosis in Infancy.

A MEETING of this society was held on Oct. 27th, Dr. T. R. BRADSHAW, the President, being in the chair.

Mr. C. G LEE showed a case of Enlargement of the Pituitary Body. The patient was a man, aged 32 years, who had been married for five years but without children. Four years ago he suffered from diabetes insipidus. His recovery was followed by general weakness and marked increase of adipose tissue, his weight increasing from 11 stones 7 pounds to 13 stones 10 pounds. Two and a half years ago the vision began to fail. On examination there was marked adiposity; no signs of acromegaly; the viscera and blood pressure were normal. There was marked optic atrophy and the fields of vision were obliterated save for small symmetrical areas on the nasal sides to 20°. There was loss of sexual power. —Dr. C. THURSTAN HOLLAND showed on the illuminated screen excellent X ray photographs demonstrating the enlargement of the sella turcica.—Mr. LEE considered that the symptoms of the patient indicated a diminution of the function of the gland.—Dr. W. B. WARRINGTON alluded to the clinical features present in five cases of this lesion which he had seen in Liverpool.—Dr. W. BLAIR BELL mentioned the differences in function of the anterior and posterior lobes, and pointed out that it was only when there was disease indicating affection of the anterior lobe or hypophysis that surgical procedure could be contemplated.—Mr. R. W. MURRAY said that the results of operation upon the hypophysis had in the last few years been encouraging. This was especially the case in the infantile types associated with excess of fat, loss of hair, and loss of sexual desire. Opening and drainage of the cyst often found in these cases had sometimes been followed by complete relief.

Dr. THOMAS BUSHBY read notes of a case in which Multiple Growths had developed in the subcutaneous tissues, associated with an Enlargement of the Thyroid Gland. The growths were extremely vascular, two of them having a distinct nævoid appearance on their summits. One of the smaller growths had been removed and the microscopical appearance favoured the view that they were metastases of an adrenal rest-carcinoma.—Dr. ERNEST E GLYNN pointed out the resemblance of the tumour to fœtal thyroid. The so-called hypernephromata were often derived from the kidney itself, not from the suprarenal rests.—Mr. G. C. E. SIMPSON

alluded to the fact that metastases from the thyroid gland might appear before signs of malignancy in the gland itself.—Dr. WARRINGTON alluded to the association of disturbance of function in the various glands with internal secretions.

Dr. J. HILL ABRAM related the clinical features of two cases of Long-continued Fever of obscure causation. He mentioned the modern methods of investigation in such cases, and stated that he attached more importance to a negative diazo reaction than to a negative serum reaction in the exclusion of typhoid fever.

Dr. N. PERCY MARSH introduced the subject of Pyloric Stenosis in Infancy by referring to the now generally accepted view that there are two distinct types of this disease, the one a true congenital pyloric stenosis, the other a condition in which pyloric spasm is first induced, and that this eventually leads to hypertrophy of the organ, with stricture of its lumen. He then described in detail the signs and symptoms as seen in five cases which had recently been under observation, especial stress being laid upon the character of the vomiting, of the stools, and the appearance of the peristaltic wave. Cases showing the excellent results which followed systematic washing out of the stomach and careful dieting were described in detail. Dr. Marsh expressed the opinion that in every case, however severe the symptoms, medical methods should first be tried; if the infant did not show improvement evidenced by diminution of the vomiting, improvement in the condition of the stools, and, most important of all, by increase in the weight, then the surgeon should be called in before the infant is so emaciated as to make any form of treatment almost, if not entirely, hopeless.—Mr. K. W. MONSARRAT demonstrated the morbid anatomy of the disease and discussed the indications for operation as illustrated by one of Dr. Marsh's cases on which he had performed a posterior gastro-enterostomy. He considered that no explanation of the lesion other than that of hypertrophy as a result of over-action had been suggested. He said that the results of diet and lavage should be tested for from seven to ten days, and then if the child was losing weight an operation should be performed. He preferred posterior gastro-enterostomy to any other proceeding.—Dr. GLYNN stated that the stenosis arose from pure muscular hypertrophy of the pylorus which especially involved the circular fibres. He mentioned a similar case in a man, aged 43 years, in which the muscle near the pyloric ring measured three-eighths of an inch in thickness.—Dr. HUBERT ARMSTRONG regarded the hypertrophy as a congenital malformation and could not conceive how spasm in the feeble pylorus of the fœtus or infant could possibly produce it. The malformation was one of excessive development and therefore need not be expected in association with other congenital defects which, with few exceptions, were those of arrest or deficiency.—Mr. R. C. DUN agreed that medical treatment should first be given a trial. Rapid improvement usually resulted where the spasm was the predominant factor. If under medical treatment there was progressive loss of weight for several days operation should be performed without delay. Cases which remained stationary under medical treatment should be operated on after three or four weeks. Posterior gastro-enterostomy was likely to prove more satisfactory than pyloroplasty.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The autumn meeting of the Northern and Midland Division of this association was held at the kind invitation of Dr. C. L. Hopkins at the City Asylum, Fulford, York, on Oct. 20th, Dr. Hopkins being in the chair.—Dr. J. Middlemass read a paper on Hereditary Syphilis and General Paralysis. He commenced by apologising for bringing forward so well-worn a subject. The idea occurred to him some time ago that in cases of general paralysis where no history of personal syphilis could be ascertained an explanation might be found in hereditary syphilis. Probably most people were of the opinion that developmental or juvenile general paralysis was due to inherited syphilis, and in the great majority of the cases he had seen there was a clear history pointing in this direction. In one such case reported the Wassermann reaction had been found to be positive. He went on to suggest that in cases where there is no history of acquired syphilis, a positive Wassermann reaction might point to hereditary syphilis and not to the untruthfulness of the patient.—In the discussion which followed Dr. Hopkins referred to the use of the Ross Jones test.—Dr. E. F. Trevelyan spoke of the relation of tabes to syphilis in families, and mentioned an interesting case.—Dr. C. K. Hitchcock considered that general paralysis depended on the temperament of the individual as well as on acquired or hereditary syphilis.—Dr. Bedford Pierce gave a most interesting account of his visit to the International Congress on Psychiatry held in Berlin from Oct. 3rd to 7th. After giving a short sketch of the arrangements made for the holding of the Congress and the cordial reception extended to the visitors, he briefly outlined the various items that were brought before the Congress, amongst which may be mentioned papers on Asylum Planning; Work as a Therapeutic Agent; The Boarding-out of the Insane—illustrated with lantern slides exhibiting its working in Hungary; The Significance of the Wassermann Reaction; Mental Diseases in the Army and Navy; Sleeping Sickness. Perhaps the most interesting features of the congress were an exhibition of models of various asylums in South Germany; kinematograph films showing the movements of the insane; and an excellent kinematograph exhibition of micro-organisms, showing in a most striking way their movements, particularly in relation to the red blood corpuscles. Amongst those exhibited in active movement were spirochæta pallida and various spirilla and trypanosomes.—Dr. T. W. McDowall thought that some demonstration similar to those shown in Berlin would be very instructive if exhibited at one of the general meetings of the association in London.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 19th, when Professor H. Alexis Thomson of Edinburgh delivered the inaugural address on "Le Rheumatisme Tuberculeux" of Poncet of Lyons. He remarked on the importance to medical men of looking on subjects through new spectacles. With this object he intended to present the ideas of Poncet of Lyons before the society. He had no doubt that the ideas of Poncet would not altogether meet with approval, but he believed that they would have the effect of stimulating thought. Briefly, all those lesions of the body to which we were unable to assign a definite pathological cause Poncet regarded as being due to a tuberculous intoxication. This, too, in spite of the fact that by no clinical or pathological process could the presence of tuberculous disease be demonstrated. In order to pave the way for Poncet's views, Professor Thomson dwelt on the pathology of joints. Eburnation of the articular surfaces had hitherto been regarded as typical of osteo-arthritis, but Professor Thomson showed a bone with ivory eburnation surrounded by caries typical of tuberculous disease. Bony ankylosis had generally been regarded as due to suppuration, yet he showed another specimen clearly of a tuberculous nature. Two specimens of bony ankylosis of the vertebral column were hard to explain except on the tuberculous hypothesis. How often, too, did they see cases of fringes and loose bodies in joints and arborescent lipomata in joints which later became typical tuberculous joints? Cases that were labelled multiple osteo-arthritis or rheumatic arthritis most commonly ended in phthisis. They generally found a tuberculous family history as well, and most of them had seen the transformation of rheumatic arthritis into white swelling. Then, too, they saw the association of undoubted tuberculous disease of one joint with polyarthritis of the joints of the fingers. Turning to clinical manifestations, they had a variety of "growing pains" or arthralgia (Poncet). These cases invariably recovered, therefore it was assumed that they could not be tuberculous. Poncet maintained they were cases of an attenuated tuberculous toxin. The cases of acute arthritis, usually polyarticular, affecting the large joints of young adults, attended by fever and uninfluenced by salicylates, might disappear and recur or become chronic, terminating in ankylosis, or might be transformed into ordinary tuberculosis. True rheumatism did not result in bony ankylosis, and Poncet declared that these cases were tuberculous. Poncet carried his theory beyond joints. From analogy of the membrane of the joints he considered that the serous membranes of the pericardium, pleura, testis, and brain, &c., might similarly become affected by tuberculous lesions and lead to tuberculous adherent pericardium, tuberculous pleurisy, and meningitis, &c. To the same origin he assigned the cause of aortitis, phlebitis, neuralgia, ocular lesions, colitis, and thickening of the pylorus. Following his theory, Poncet declared that these cases did better on an antituberculous treatment than on a spa treatment. Although finding it difficult to agree with al

Poncet's theories, Professor Thomson thought that they should recast their views of these lesions in their practice.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—At the opening meeting of this society an interesting presidential address was delivered by Dr. William Mitchell upon Diagnosis by Means of X Rays. He said that the discovery of the X rays by Roentgen had made a great addition to our methods of diagnosis. The last five years, by the improvement in apparatus, had immensely increased the possibilities of this form of diagnosis. Fluoroscopy and skiagraphy were the chief methods employed. Fluoroscopy had the advantage of a direct inspection of an object which could be moved while being examined, but it was difficult to get detail, and might be dangerous owing to the difficulty of cutting off undesired rays. Skiagraphy, with modern instruments, was rapid, almost instantaneous; great detail was possible, and the disadvantage of a picture in one plane could be got rid of by stereoradiography, by the projection methods of Mackenzie and others, and by photography in planes at right angles. Difficulties still remained to those who could not afford a series of tubes of different degrees of "hardness" and in all cases of stout patients. By the use of these processes we could discover and localise: (1) foreign bodies, if metallic, glass (calcium or lead, but not potash or soda), but not wood; (2) fractures and dislocations; and (3) various pathological conditions in (*a*) bone, e.g., caries, gumma, growth; (*b*) soft tissues, dense fibromata or calcified deposits; (*c*) lungs, phthisis, tumour, pneumonia, mediastinal growths, pleural and pericardial effusions, displacements of heart, vessels, and diaphragm, and aneurysm. In the abdomen there was a small range of possibilities, owing to the density of the organs. Thus aneurysm would be demonstrated only by erosion of vertebræ. In the alimentary system the teeth gave good pictures, caries being readily visible, and the use of bismuth carbonate in doses up to 4 ounces, suspended in porridge or otherwise, revealed strictures and diverticula of the œsophagus, gastric dilatation, enteroptosis, and hour-glass contraction. Gall-stones except when coated with lime were almost invisible, but renal, ureteral, and vesical stones could be made out with almost absolute certainty. It was important here to have the landmarks afforded by the muscles, the ribs, and the transverse processes, and to avoid the fallacies of calcareous glands. In neurology cranial tumours, unless ossifying or arising from bone, were not visible, but the osteoclastic results of tumour, as in pituitary tumours, were easily made out. The condition of the sella turcica could also be made out in cases of acromegaly. Examination of the spinal column was not easy, but in children and in the cervical and lumbar regions valuable results had been obtained which had a bearing on nervous conditions. Eighty lantern slides made from skiagrams and some stereoscopic skiagrams were then shown.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Oct. 7th, Mr. F. Lace, the President, being in the chair.—Dr. A. J. B. Leckie showed Specimens of an Ovarian Fibroid Undergoing Calcification and Cystic Degeneration weighing 30 pounds, and a Sarcoma of the Left Kidney involving the twelfth dorsal and first lumbar vertebræ, right kidney, and liver, weighing 4 pounds 10 ounces, which had been removed from a child, aged 4½ years, after death, whose weight three weeks before she died was 21 pounds.—The President then gave a short Introductory Address.—Dr. F. G. Thomson read a paper on a case of Acute Toxic Polyneuritis in a boy aged 19 years. Paralysis first affected the hands and feet and within ten days of onset caused complete palsy of all four limbs and of both sides of the face. The muscles of the neck, the intercostals, and the lumbar muscles were also extensively paralysed. Sensory symptoms were confined to slight numbness of the fingers and the soles of the feet. The deep reflexes were lost. Considerable wasting occurred in the scapular muscles and the muscles of the forearms and legs. The extensors of the fingers and toes especially suffered. Recovery was complete in two years from the onset. Treatment consisted in rest, good diet, massage, galvanism, and faradism. Strychnine was given from time to time.—Dr. T. Wilson Smith read a paper upon Some Varieties of Intermittent Albuminuria. Referring to postural or orthostatic albuminuria he pointed out that none of the theories of its causation seemed completely satisfactory. He had watched some cases of postural albuminuria over periods reaching to 19 years, but had not seen degenerative cardio-vascular changes occurring, nor the tendency to faint when in the upright position which Dr. Clement Dukes had described. He had, however, noticed lassitude, aching across the loins, anæmia, loss of appetite, and in one case prolonged attacks of nausea and vomiting. Referring to intermittent albuminuria due to substances passed in the urine, which irritated or injured the renal epithelium, he detailed cases of oxaluria after copious ingestion of strawberries, &c., producing temporary albuminuria; also cases due to copious passage of uric acid crystals, in some cases forming complete casts of uric acid.—Dr. Leslie H. Walsh read notes of a case of a Transient Unilateral Swelling in the Right Parotid Gland, in all probability of nervous origin.

Reviews and Notices of Books.

Practical Pathology. A Manual for Students and Practitioners. By G. SIMS WOODHEAD, M.A. Cantab., M.D. Edin., Hon. LL.D. Toronto, Fellow of the Royal Society, Edinburgh; Professor of Pathology in the University of Cambridge. Fourth edition. With 275 coloured illustrations. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 798. Price 31*s.* 6*d.* net.

Professor Woodhead's well-known book on Practical Pathology has long been out of print, and we welcome the appearance of this new edition, for no other work has appeared quite to replace it or to give in such an original, interesting, and thoroughly practical manner the information which the student and practitioner alike seek in a manual of pathology. While retaining its original aims and general form it has obviously been carefully revised and largely rewritten so as to incorporate the many new methods which have been introduced, and the advances in our knowledge of pathological processes which have accrued in the 18 years that have elapsed since the publication of its predecessor. To say this is practically to say that we are reviewing a new book.

The chief features of Professor Woodhead's book, which invest it with its special character, are the admirable descriptions given of the morbid anatomy and histology of diseased organs, the clear though concise accounts afforded of pathological processes, and the excellent coloured illustrations of microscopical specimens with which the book abounds. These illustrations are of a very high order and reproduce with remarkable fidelity the appearance of specimens prepared and stained by special methods.

The first chapter describes the technique of post-mortem examinations and the various special methods necessary to expose the different organs. General directions are also given for the collection of material for bacteriological and microscopical examination. The second chapter contains full details (including the formulæ of all reagents employed) of all the ordinary and of the most important special methods employed in the preparation of specimens for microscopical examination. These descriptions are worthy of special commendation, since they are given in such a manner as to be practical, for in each case it should be easy to carry out the method from the directions given.

In dealing with the results obtained from a practical study of pathological processes, Professor Woodhead first treats of the subjects of inflammation, organisation, and repair. He describes the various cells found in the blood, in inflamed and irritated tissues, and indicates what is known of their origin and functions. He next considers the results of inflammation in certain serous membranes, and then describes the healing of wounds and of ulcers. He then brings out clearly the relation of inflammation to repair, so that a student carefully working through this chapter should be

able, with the aid of specimens, to get a very clear idea of these fundamental pathological processes.

The morbid processes in the various organs and systems of the body are then described categorically in separate chapters. The various diseases of the liver are first considered; among these the account given of the forms of cirrhosis and of the stages of the interstitial changes causing these conditions may be specially mentioned as being more simply and clearly classified than is often the case in text-books on pathology. The morbid changes in the heart are next examined, and the various degenerations, infiltrations, and inflammations are clearly differentiated and described. The chapter on diseases of the blood-vessels which follows gives a useful account of the changes in atheroma and endarteritis obliterans, the latter condition being described as it occurs in syphilis, in healing wounds, interstitial inflammations, and in Bright's disease.

In the section on diseases of the alimentary canal an interesting account of the various forms of ulceration is given, and the distinctions between tuberculous and typhoid ulcers are given in tabular form. In the section on bones and joints a clear description is included of the changes in rickets, but it is a little surprising to find infantile scurvy referred to as "an exceedingly acute form of rickets." The chapter on the nervous system is short in comparison with its importance, but it contains some excellent illustrations. Tumours and parasites are also dealt with, and a considerable amount of valuable information is afforded. The plates showing the parasites of kala-azar, of syphilis, and of sleeping sickness are also worthy of notice.

Professor Woodhead's book is a valuable addition to the student's and to the practitioner's library.

The Medical Complications, Accidents, and Sequels of Typhoid Fever and the Other Exanthemata. By HOBART AMORY HARE, M.D., B.Sc., Professor of Therapeutics in the Jefferson Medical College of Philadelphia, and E. J. G. BEARDSLEY, M.D., L.R.C.P. Lond., Assistant Physician to the Out-patient Department of the Jefferson Medical College Hospital. With a Special Chapter on the Mental Disturbances following Typhoid Fever, by F. X. DERCUM, M.D., Professor of Mental and Nervous Diseases in the Jefferson Medical College. Second edition. Philadelphia and New York: Lea and Febiger. Pp. 406. Price $3.25.

IN the first edition of this work the authors pointed out that although systems of medicine and text-books innumerable deal with the ordinary manifestations of typhoid fever, the references to its accidents, its complications, and its sequels are necessarily brief. Nevertheless, anyone who has had even a limited experience with this disease has met with cases in which the malady has been so altered in its course by intercurrent affections as to be quite unusual, and to call forth all the knowledge in diagnosis and therapeutics the physician possesses. The work now under consideration deals in a comprehensive and instructive manner with these aberrant forms and the courses they may pursue. During the ten years which have elapsed since the first edition appeared the literature dealing with typhoid fever has greatly increased, and the advances which have been made in the study of the disease by bacteriological methods have added considerably to the knowledge of many of its complications and sequels. The book has been punctiliously brought up to date and will be found of real value as a work of reference. The chapters on "Varieties of Onset" and on "The Complications of the Period of Convalescence" are of especial interest. In this edition chapters dealing with the complications and sequels of variola, scarlet fever, measles, chicken-pox, and rubella have been carefully prepared and added to the original text. In discussing variola especial attention is rightly drawn to "the prodromal rashes and dermal complications" of this disease. These rashes vary widely in type and often serve to obscure the true diagnosis for hours, and it may be for several days. It is important that such eruptions should be known and recognised. A good account is given of them in this work, and a study of the descriptions given will be of use in actual practice. In scarlet fever the complications and sequels are probably more numerous and important than in any other of the infectious fevers, with the exception, perhaps, of typhoid fever. Rhinorrhœa, otitis, ulcerative stomatitis, tonsillitis, adenitis, nephritis, ulcerative and gangrenous angina, broncho-pneumonia, ocular complications, and other conditions occurring in connexion with scarlet fever are well described and discussed.

The chapter on the mental complications of typhoid fever, by Dr. F. X. Dercum, will be found of considerable interest. He divides these mental disturbances into three groups: (1) those which develop during the prodromal or initial period; (2) those which arise during the continuance of the fever; and (3) those which occur during or subsequent to convalescence. The forms of insanity which arise during or subsequent to convalescence are the most important and are described in detail. The remarks on prognosis are interesting. Dr. Dercum is of opinion that the prognosis depends largely upon the period at which the symptoms appear. Prodromal insanity, especially grave prodromal delirium, tends in a large number of cases to end fatally. The prognosis of the mental complications arising during the fever is almost uniformly good. The various forms of mental derangement which occur as sequelæ of typhoid fever also offer a favourable prognosis as a whole, although in some cases recovery is incomplete, and other cases may pass into hopeless chronicity and dementia.

It will thus be seen that this volume contains much that is interesting to those engaged in general practice, and in it are presented in compact form a description of many problems that may well puzzle those who have not had an exceptionally large experience of the infectious fevers.

The Public Milk-supply. By HUGH A. MACEWEN, M.B. Glasg., D.P.H., Assistant Medical Officer of Health, Cumberland. London: Blackie and Son, Limited. 1910. Pp. 182. Price 2*s.* 6*d.* net.

THE author has brought together a great deal of information as to the practical details of milk-supply in this well-illustrated manual. He has had exceptional opportunities of becoming familiar with the practical side of dairy farming; and if farmers, cowkeepers, and dairymen would make themselves acquainted with the improved methods that have of late years been brought into use for the protection of this indispensable article of food-supply, and that are here described and figured, much good would result. Dr. Macewen adopts the very sensible position that the present 3 per cent. standard for fat in milk is unsatisfactory; not that a genuine sample of mixed milk is likely to fall below this standard, but because it is possible that individual samples may occasionally do so, without any fraudulent practice; and because it is not fair that a farmer who sells rich milk, containing perhaps 5 per cent. fat, should get no more for it than his neighbour, whose cow yields milk containing the bare minimum. "Milk sent to creameries is paid for according to the amount of fat it contains. Why should not milk be sold for ordinary consumption in a like manner?" The distribution of milk in sterilised bottles is advocated, the milk having been previously strained and chilled. On p. 79 we read: "So-called sterilised milk refers to milk that has been simply boiled, and it is in that sense that we shall continue to use" the expression. This, however, is not

accurate; milk may be sterilised without being boiled, and boiled milk is not necessarily sterile. The author quotes the statement that the constant use of boiled milk has been known to give rise to rickets, adding that the results obtained in connexion with infant milk depôts where the milk has been pasteurised have not always been satisfactory. More details might have been afforded on this debated question, and the relative importance of the risks from polluted raw milk and from treated milk considered. Admitting the possibility of harm to the infant from feeding with treated milk, one must also allow that suitable precautions can be taken; while at present the dangers of a raw milk-supply for town children are more numerous and important and far more difficult to guard against. The information as to the housing of dairy animals is very useful and the illustrations are excellent. A special section is devoted to the law of milk-supply. Dairy products are but lightly touched on, and more information might have been given about butter; the quantity of salt used is not mentioned. A useful summary of the law relating to adulteration is appended.

Surgery and Pathology of the Thyroid and Parathyroid Glands. By ALBERT J. OCHSNER, A.M., LL.D., Professor of Surgery in the Medical Department of the University of Illinois; and RALPH L. THOMPSON, A.M., M D., Professor of Pathology in the St. Louis University School of Medicine, St. Louis. With 57 illustrations in the text and 40 full-page plates, 4 of the plates being in colours. London: George Keener and Co. 1910. Pp. 391. Price 25*s.* net.

ALTHOUGH goitre has been known for more than 2000 years, a very little time has elapsed since it was first recognised that the thyroid gland had a definite function, and that its presence, or the presence of a portion of it at least, is necessary for the health of life. The recognition of the true cause of cachexia strumipriva was really the starting point of the appreciation of the physiology and pathology of the gland. In many cases an enlarged thyroid is merely a source of discomfort to the patient because of the unsightliness which it causes, but cases do occur in which the enlargement is so great that it interferes materially with respiration or even with deglutition. In cases such as these, and even where no real interference with vital processes exists, the question of operative interference has to be considered; and the importance of the operation has fully justified the devotion within recent years of several text-books to the special study of the surgery of the thyroid gland.

The chapter on the history of the gland is of interest, the account of its development and its pathology is clearly written, and the series of plates illustrating the anatomy of the region of the thyroid as seen in successive stages of the dissection will help to make clear to the student the structures to be avoided in operations on the gland. The most important portion of this part of the book relates to the technique of the operation of excision. The authors believe that a general anæsthetic is preferable to any form of local anæsthesia, and the incision they recommend is horseshoe shaped, commencing a little above the upper border of the larynx on the one side near the anterior border of the sterno-mastoid, descending to about an inch above the upper margin of the sternum, and then rising again to a point on the other side corresponding to that from which it started. This incision certainly provides the surgeon with a very clear view of the field of operation. The several steps of the operation of excision are clearly described, the dangers which may be encountered are mentioned, and the methods of evading them are given. It is advised that a glass drainage-tube, surrounded by a layer of gauze, should be placed in the lower part of the wound or through a separate opening below.

The remaining portion of the book is devoted to the study of the parathyroid glands. These glands have been the subject of much controversy, some regarding them as of vital importance, and others looking upon them as merely undeveloped thyroid tissue. It must be confessed that a tendency of the present day is to appraise them as of more importance than formerly, and it is probable that the majority of those who have specially studied the subject will agree with the statement that complete removal of the parathyroid tissue results in the production of tetany. This is certainly the most elaborate account of the surgery of the parathyroids that has up to the present been published. Dr. Thompson describes the anatomy of the glands not only in the human subject but in many of the lower animals; the embryology and histology are given, and are followed by the pathology, but no definite suggestion is made as to their physiology. Cysts and tumours of the glands are described, and then comes an important chapter on the tetany which follows operative removal of these glands. He then describes what he calls somewhat curiously "mental tetany," that is to say, tetany arising apart from injury or operation, and he considers that in cases in which tetany follows dilatation of the stomach hypertrophy of the parathyroids is present. The chapter on parathyroid therapy is suggestive and contains references to most of the papers on the subject, and a useful and extensive bibliography of the parathyroid glands concludes the volume.

The book is well written, and, as might be expected in a subject still comparatively new, many views are expressed to which exception might be taken, but the authors in most cases are able to give good reason for the opinions they hold.

Handbuch der Vergleichenden Physiologie. (*Handbook of Comparative Physiology.*) Herausgegeben von HANS WINTERSTEIN in Rostock. Jena: Gustav Fischer. 1910. Band II., Erste Hälfte (Bogen 1–30), pp. 1–482 (1st, 2nd, and 3rd Lieferungen). Band II., Zweite Hälfte (Bogen 1–10), pp. 1–160 (4th Lieferung). Band II., Zweite Hälfte (Bogen 11–19), pp. 161–304 (5th Lieferung). Price 5 marks each part of ten sheets. The work will consist of about 30 "Lieferungen," or parts.

WHILE there are plenty of books and treatises on physiology—general and special—and also on bio-chemistry, there is, as yet, no completely comprehensive treatise on comparative physiology. The limits of the late "fifties" (1857) when Milne Edwards published the first volume of his "Leçons sur Physiologie," no longer bound our knowledge of this subject. Its importance is becoming recognised more and more, and indeed it must form the basis of all human physiology. Therefore both editor and publisher are to be heartily congratulated on this new and important venture, and we trust that both will reap their due reward. We wish this "Handbuch"—it is really an encyclopædia—every success. It not infrequently happens that when a large work like this is projected the editor proposes and the contributors—of whom in this case there are twenty in all—"dispose," and hence perhaps the reason why, instead of Vol. I., we have only the major part of Vol. II. (in five parts) before us, each part being composed of ten sheets, or 160 pages. When the work is complete it will consist of four volumes. Vol. I. will deal with the "Physiology of the Fluids of the Body and Respiration," Vol. III. with the "Production of Energy" and the "Physiology of Form," and Vol. IV. with the "Physiology of Sense Receptors, Conduction, and Response."

Up to the present time comparative physiology has been more or less like a partially explored continent, and even such data as have been obtained have not been arranged and codified systematically. The "Lehrbuch der Vergleichenden

Physiologie der Hausthiere" of Ellenberger and Scheunert (1910) is a text-book and deals only with the domestic animals. The general scheme of the present editor has been to leave to each contributor a free hand, but with the editorial injunction to keep in mind the "classes" of the animal kingdom, beginning with the protozoa and considering each class in detail. Again, he was faced by certain limits, botanical on one side; physiology of man and the higher animals, so far as this is treated of in the ordinary text-book, and morphology on the other.

Vol. II. deals with the physiology of metabolism and of reproduction. To Professor Biedermann of Jena is entrusted the subject of the "Intake, Elaboration, and Assimilation of Food," to which nearly 500 pages are devoted. No better "Fachmann" could be found than the versatile and erudite successor of Preyer. Starting off with a masterly account of the nutrition of plants and its relation to that of animals, including assimilation in chlorophyll-free plants, we are led on to the researches that deal with the assimilation of carbon, nitrogen, sulphur, and phosphorus in yeasts and moulds, and further on to what is practically a treatise on bacteria in all their varied functions, their chemistry and choice of food. Then follows a general review of the whole matter so far discussed and a long list of works of reference—an arrangement that is adopted in succeeding chapters. The down-grade processes of dissimilation, as determined by bacteria, are included, with a full discussion of the various fermentatations due to bacteria—the alcoholic, lactic, butyric, and other fermentations—the action of enzymes, proteolytic, fat-splitting, and those that act on carbohydrates; in fact, a full treatise is supplied on enzymatic action in all its varied phases, including a very full account of oxydases, making a comprehensive and interesting chapter. The author expresses himself guardedly regarding the probable action of animal oxydases, as the data are not sufficiently numerous. Then we touch upon the interesting subject of the dependence of enzyme formation on the kind of food used, a problem best known to human physiologists by the work of Pawlow, though bacteriologists have long been acquainted with corresponding results.

The second part deals with the Nutrition of the Protozoa as represented by the rhizopoda, gregarinæ, flagellata, and ciliata. A very full account is given of the work of Bütschli, Verworn, Rhumbler, Jennings, Jensen, Schaudinn, and others who have devoted much attention to the study of these ever-attractive unicellular organisms. The subject is one that interests all physiologists, zoologists, and botanists, for here is common ground. Here also the physicist comes in, for have not Berthold and Quincke given a theory of the importance of surface-tension in the intake of food by some of these lowly protoplasmic organisms? Not the least interesting are the classical experiments of Rhumbler, on the engulfing of a thread of shellac by a drop of chloroform and allied physical experiments.

Naturally, the infusoria are fully dealt with, and, in fact, the greater part of the third fascicule is taken up with this subject. The nutrition of sponges forms the third part, and it is treated in the same thorough manner (pp. 426–444), also with a full list of the chief papers added. Nearly 50 pages are devoted to the physiology of the cœlenterate group, but the third fascicule only takes us to actinia; and we must wait until the continuation of this subject is published. If the remaining "classes" of the animal kingdom are treated as fully then we may expect at least one other "Lieferung" on this subject.

We have before us also two parts of the second half of Vol. II. All Part 4 and by far the greater part of Part 5 are given up to a most interesting and comprehensive survey of the following subject, the Secretion of Protective and Useful Products, by Professor Fredericq of Liège, whose many-sided scientific and literary activities make him admirably adapted to deal with such a wide and fascinating subject. He deals with the subject from protozoa to mammals. The recent work of Richet on the poisons of actinia and their allies is introduced. It would be impossible to give in short compass a survey of the extraordinary mass of information which has been grouped in this form for the first time. Under the head of diseases supposed to be associated with fish diet we miss the name of Jonathan Hutchinson, and in the chapter on birds John Hunter's observations of the secretion of the crop of pigeons does not seem to be mentioned. The fifth part concludes with about 50 pages devoted to "the secretions"—i.e., the non-gaseous decomposition products, excluding unabsorbed nutriment, by R. Burian of Naples, whose researches on uric acid are so well known.

We can only repeat that this work is an encyclopædia—a vast storehouse of carefully garnered and correlated facts, which we feel sure will be gladly welcomed by all workers in physiology and zoology. We have nothing but praise for so commendable an enterprise and we wish it the marked success which it deserves.

LIBRARY TABLE.

Ionic Surgery in the Treatment of Cancer; with a Chapter on Ionisation in Surgical Tuberculosis and in Hæmorrhoids. By G. BETTON MASSEY, M.D., Attending Surgeon to the American Oncologic Hospital. London: Siegle Hill and Co. 1910. Pp. 243. Price 13*s.* net.—The value of the ionic treatment of disease is as yet not fully appreciated in this country, but it is probable that in the future it will be employed more widely than at present. This book, however, does not deal with the whole subject of ionisation in the treatment of disease, but it deals almost exclusively with the endeavour to treat malignant disease by means of metallic ions. Without going into the details of the method employed we may say that the process as described by Dr. Massey consists in introducing a metallic electrode coated with mercury into the substance of the growth and then passing a current through it to another pole placed on some other part of the body. Currents of several hundred milliampères are employed and anæsthesia is generally required. The author records and figures a number of cases in which he has employed the method. In most of those in which the growth was on the face successful results appear to have been obtained. With regard to malignant disease of the breast, improvement is recorded in many cases, and there are a few in which patients have lost all evidence of disease, but most of these are very recent. While agreeing that the method deserves a trial in some cases, we would urge that it should not be employed for operable cases, at all events in the present state of our knowledge.

A Practical Treatise of Diseases of the Skin for the Use of Students and Practitioners. By JAMES NEVINS HYDE, A.M., M.D., Professor of Dermatology in Rush Medical College, Chicago; Professorial Lecturer on Diseases of the Skin, University of Chicago, &c. Eighth and revised edition. Illustrated with 223 engravings and 58 plates in colours and monochromes. London: Baillière, Tindall, and Cox. Pp. 1126. Price 25*s.* net.—The text-book which has appeared during several editions under the joint authorship of Dr. Nevins Hyde and Dr. F. H. Montgomery achieved a world-wide reputation as a very trustworthy treatise on this difficult subject, and the present volume is a fresh edition which has been issued by Dr. Hyde alone, for he has been deprived by death of the help of Dr. Montgomery. The progress of dermatology

has required that the present volume should contain 250 pages more than the seventh edition, and we cannot say that any of the added material could well have been omitted. The main additions to the work have been many and some rearrangement has also been carried out; thus the growing importance of tropical diseases has induced Dr. Hyde to collect these affections together, and in the same way the affections of the nails. It is unnecessary to discuss fully so well-known a treatise, but we may say that it is a trustworthy account of the diseases of the skin, that it is written with moderation, and that the author is not afraid of expressing his own opinion. It is well illustrated both with black and white and coloured plates, and it can be thoroughly recommended to all who require something more than an elementary treatise on dermatology.

Saint Bartholomew's Hospital Reports. Edited by H. MORLEY FLETCHER, M.D Camb., and W. MCADAM ECCLES, M.S. Lond., F.R.C.S. Eng. Vol. LXV. London: Smith, Elder, and Co. 1910.—This volume is full of interesting papers. It commences with obituary notices of Sir Thomas Smith and Dr. W. J. Russell. Some interesting cases from the skin department are described by Dr. H. G. Adamson and a number of cases of artificial dermatitis are figured. Dr. Harold Pritchard describes a case of infective endocarditis due to a hitherto undescribed organism. A valuable paper is that on splenic anæmia by Dr. R. A. P. Hill; he comes to the conclusion that splenic anæmia includes two conditions: one of these is pernicious anæmia with enlarged spleen, and the other is splenic lymphadenoma; yet he looks upon the two conditions as varieties of the same disease, and he suggests that splenectomy should be used in the treatment of pernicious anæmia. Mr. A. J. Clark's paper on the detection of blood pigment in the fæces is likely to be useful, and he claims that the smallest quantity of blood entering the bowel, either in the food or by hæmorrhage, can be recognised in the fæces. Mr. W. Bruce Clarke reports two cases of lymphangioplasty; in both of them successful results followed. Mr. C. B. Lockwood has written on the surgical treatment of tuberculous mesenteric glands. Mr. C. Gordon Watson has analysed all the cases of perforation in enteric fever which have been operated upon in St. Bartholomew's Hospital up to the end of 1908. These are 27 in number and five recovered. The remaining papers consist of reports on X ray dermatitis: Dr. H. Lewis Jones writing on the avoidance of X ray injuries; Dr. H. G. Adamson on X ray dermatitis as it is related to dermatology; and Mr. L. Bathe Rawling writing on the surgical aspect of the condition. This group of papers is of the greatest value and gives an accurate statement of our present knowledge of the subject. The remainder of the volume deals with the registrars' reports and the additions to the museum.

Speech-Reading for the Deaf—not Dumb. A Book for the Use of those who have become Deaf after having acquired a Full Knowledge of the English Language. By A. J. STOREY, Headmaster of the North Staffordshire Blind and Deaf School, Stoke-on-Trent. London: Yellon, Williams, and Co., Limited; The Celtic Press, Chancery-lane, W.C. 1910. Pp. 166. Price 5*s.* net.—One of the greatest afflictions not of a mortal nature which may oppress the old or even those yet in middle life is the loss of the power of hearing. Many have questioned whether even blindness itself is not a less affliction than deafness. Whether this be so it is at least certain that to lose more or less completely the sense of hearing is a great deprivation, and therefore any means whereby the deaf man will be able to interpret what others say should prove an inestimable boon. The method which appears to be best suited for this is the learning of lip-reading, and this is comparatively simple to those who have already learned to speak. This book is, we think, the first that has been written with the object of teaching lip-reading to those who possess the power of speech; and it is admirably calculated to carry out its purpose. After a few chapters devoted to introductory matter, the science of speech, and the principles of lip-reading, a series of lessons is given on the various groups of sounds, and the student is instructed in apprehending the meaning and the interpretation of lip movements. The exercises are well chosen and they initiate the student gradually into the whole subject, and very useful hints are given for the prosecution of the study. We feel sure that the book will prove of immense use to many people. Deafness is often a great trial, not only to the deaf person himself, but to those who associate with him, and a careful study of the subject should give results which will prove of very definite benefit. Even when deafness is not severe the power of lip-reading may prove of value.

JOURNALS.

The Baby's World: a Practical Magazine for Mothers. Edited by J. JOHNSTON MACGREGOR. London: Ewart, Seymour, and Co. Price 6*d.*—The number for October completes the first half-year of the publication of this magazine, which aims at being a source of information with regard to everything a mother requires to know about herself and about the proper feeding, clothing, management, and education of her children. "The Rod and Pickle" is the title of a series of articles by Mary Cornwall on the Moral Education of Children, which promises to deal with this subject from a sensible point of view, not looking upon discipline as a punishment for the fault or a deterrent from future misdoing, but as the means of making a child realise the essential wrongness of particular acts and the unhappiness that follows the committal of a misdeed. The necessity to discriminate between faults and acts that are merely affronts to parental pride, and to appreciate the differences between wild, strong emotions and moral deficiencies is clearly pointed out, and the danger of moral precocity is not forgotten, for like the mental and physical, the moral nature of a child cannot be expected to mature in childhood, and a moral precocity is as likely to be followed by moral degeneration as is a mental or physical precocity. Such sensible articles as these will be read with profit and thoughtfulness by many parents who are in doubt as to the right course to pursue in checking or keeping within bounds those evidences of naughtiness which are often only the expression of uncontrolled and miniature emotions belonging to what may eventuate in a really fine character. We are of opinion that medical and surgical subjects cannot be written about in periodicals of the character of *The Baby's World* without either unduly alarming or dangerously informing the public upon medical and surgical points. Without a comprehensive knowledge of pathology and a familiarity with biological and physiological science it is impossible properly to appreciate etiological and therapeutical problems, and we cannot look with any approval upon the article entitled "A Mighty Atom" written by a medical man, and telling how the "tiny tubercular bacillus" affects the glands, joints, brain, and bowels of children.

THE NATIONAL FOOD REFORM ASSOCIATION.—The conference of matrons of hospitals and similar institutions, which the National Food Reform Association is convening, takes place at Caxton Hall, Westminster, to-day, Saturday afternoon, Nov. 5th. Miss Rosalind Paget will take the chair at 2.30 P.M., and a paper on the "Feeding of Nurses" will be read by Miss Musson of the Birmingham General Hospital.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 5, 1910.

Plague in Rats and Man.

THERE is no longer any ground for doubting that plague amongst rats is somewhat widely distributed in one corner of Suffolk, although its limitations cannot be determined until further investigation amongst the rodents in adjacent districts has been carried out. But enough has already been discovered to show what an extensive area may be involved in the matter of plague in rats without more than a single group of human cases occurring, and this in itself is a very reassuring circumstance, indicating how difficult it may be in this country under existing circumstances to bring about infection of human beings. Not only is the rat malady widespread but we have no precise knowledge as to how long this condition of affairs has obtained. There is apparently an impression locally that rat disease may have existed for many months or perhaps even longer, and the local press is searching the disease and death records of the past with the object of discovering cases suspicious of the human malady. Even if all such cases were to be accepted as positive no very startling results would be produced. But the fact must never be lost sight of that in India, China, and other countries where plague occurs the disease amongst rats is frequently associated with the same disease in the human species, while experience demonstrates conclusively that the rat disease may cause plague in man both by direct inoculation and through the medium of the flea.

That plague in India is frequently associated with and produced directly or indirectly by rat plague is certain, but there appears to be still room for further investigation with reference to the occurrence of plague in rats during periods when no human plague exists. Great Britain herself is not without previous experience of plague amongst rats, and in the year 1901, out of 1641 rats examined at Glasgow 30 were found to be infected. During the next four years there were nearly 3000 rats examined, and all with negative results; while in 1907, out of 7000 examinations one was found to have plague—a fact, slender though the connexion be, which leads to the reflection whether this solitary animal was the last dying ember of the 1901 outbreak or whether it was the result of some re-introduction of infection. Again, in the port of London between August 19th and Sept. 28th, 1908, of 162 rats found dead in certain of the warehouses several had died from plague. Researches made by Dr. KLEIN showed that this epidemic was of a mild and chronic character with a low degree of virulence, and while many persons were exposed to infection from these rats only one showed any signs of plague. Other illustrations of similar phenomena are to be found in the bibliography of plague, and these taken together rather point to the conclusion that plague amongst rats in a chronic and non-fatal form may have been more widely prevalent than has been generally recognised. The experience of rat plague in this country, and also in Australia, where, however, the mortality amongst human beings was sufficiently serious, seems to justify the conclusion that highly civilised populations, with the resources at their command and their sanitary habits, need have no apprehension of the results which accrue amongst Asiatic populations with their insanitary mud-floored and overcrowded dwellings and with their bare-footed inhabitants. But, in addition to these facts, there are other considerations which may have occurred to many of our readers who have been reflecting upon the Suffolk phenomena. For instance, Dr. C. J. MARTIN, of the Lister Institute, has drawn attention to the fact that the Indian or black rat, which formerly inhabited this country, has been largely swept out by the more voracious Norwegian or brown rat which, unlike the black rat, which is a house rat, largely frequents sewers and docks, and therefore is not, except in the docks, brought much in contact with man. This is certainly an important fact, but we gather that rats dead from plague have been found at considerable distances inland, a fact which would lend colour to the views of those who hold that the black rat is by no means so nearly extinct as is popularly imagined.

A matter of some bearing on the present prevalence of plague among rats in the eastern counties is the ability or inability of the rat to traverse the wide expanse of water presented by the estuary of the Orwell. Those who believe in the actual extermination of the rat over the area in which it was first found to be infected base hope upon the water-bound character of the country thereabouts. But we are afraid that their efforts may be attended by disappointment, inasmuch as rats pressed by hunger or pursuers will traverse bodies of water at least as wide as any of the estuaries in this country; indeed, it is related that rats have been observed at night crossing in swarms the waters of the Limfjord, a wide channel in Jutland, and these vermin are said to have been frequently seen swimming *en masse* across the straits separating the islands of the Faroe Archipelago. All these reflections are replete with interest for the naturalist, and the sanitarian may later have to take them into account, but at the present juncture there is an obvious duty which devolves upon the local authorities in compassing by every means in their power the destruction of the rat population in the respective districts, and by the frequent removal of refuse to discourage the presence of these vermin in the vicinity of dwellings. All experience points to the conclusion that if rats be kept outside the house the risk of plague infection is extremely remote, and the question of rendering the homes of the poor rat-proof by means of cement flooring may well be considered in future construction. Rigid cleanliness in the humbler quarters must be enforced, particularly in quarters where fleas and other dangerous insects are known to abound. The large landowners and their tenants in Suffolk will, no doubt, heartily coöperate with the local authorities in such schemes as they deem it best to adopt, but it is for the local authorities to organise matters and take the lead, and to galvanise into activity smaller holders of land who may not be playing their proper share in

the war towards rat extinction. Provisional arrangement should be made for isolation and observation, and persons intimately exposed to infection from rats, or possibly infection from human sources, should have an opportunity of obtaining such protection as plague prophylactics will afford them. If all these precautions be duly enforced no very great anxiety need be experienced by the human inhabitants of the invaded districts, although it must frankly be accepted that the position is fraught with some danger. A fact of good omen, upon which, however, too much stress must not be laid, is the difference between the rat flea in India and the rat flea in this country. The Indian parasite betakes itself not unwillingly to the human host, whereas the rat flea of this country has but a poor appreciation of the blood of man. There is certainly something in the behaviour of the malady in Suffolk which suggests some such explanation as this would afford.

Vaginitis in Hospitals.

OUR attention has been called, through a reference to THE LANCET therein, to an article published by a paper called *Mrs. Bull* on Oct. 29th, and headed "Great Ormond-street Children's Hospital," and having for its subtitle the following: "Shocking Disclosures — Little Children infected with Foul Disease—Lame Excuse of the Authorities." Where we come into this galley is the fact that a special commissioner was sent by the proprietor or the editor of *Mrs. Bull* to investigate certain complaints with regard to the treatment at the Children's Hospital of two small children at the beginning of this year, and a conversation having ensued between the commissioner and one of the hospital authorities, the medical man suggested that the matter was one for discussion in THE LANCET rather than in a lay paper. From our point of view, having carefully gone into the questions at issue, it seems doubtful whether there is any real need to say anything, but in accordance with our oft-expressed view that allegations against our medical charities ought to be discussed with even unnecessary freedom so that the public which supports them may judge of their conduct, we accept the reference to ourselves in the matter.

What actually occurred at Great Ormond-street Children's Hospital is as follows. In November, 1909, a case of vaginitis was admitted to the wards, and before it was recognised and isolated the infection had spread, and seven cases had to be dealt with. All these cases were isolated and treated in accordance with the usual and very strict routine—for, of course, the risk of this infection is extremely common—and all recovered. On Jan. 6th, 1910, a female child, A, aged 4 years (who entered the hospital, by the way, with a "dirty head"—that is, with pediculosis capitis), was operated upon for tuberculous glands, and three weeks later was sent to Cromwell House, Highgate, the convalescent home of the hospital, having then a clean head and no vaginitis. On March 17th she was received back at the hospital, and as she was found to have developed vaginitis she was isolated in the strictest manner until for three weeks she appeared to have been free from the malady. She was not sent home to be undressed by a surprised mother, as stated by the writer in *Mrs. Bull*. She re-entered the wards, but still with the special supervision accorded to possibly infectious cases, and finally went home on June 1st, having then apparently no vaginitis and a clean head. On June 28th she was re-admitted with a "dirty head" and a recurrence of her obstinate malady, was again strictly isolated, and at length the condition was cured. Concurrently with this case there was under treatment for pneumonia a little girl, B, aged 3 years. She was admitted to the hospital on Feb. 11th, and on Feb. 24th had sufficiently recovered to be sent to the convalescent home at Highgate. From there she went home on March 17th, but almost immediately was found to be suffering from vaginitis. She was re-admitted into the hospital, was isolated, and her condition, like that of the other child, yielded to treatment, though a relapse has followed. On these two cases, with perhaps a vague suggestion that the outbreak in November, 1909, was a serious one, an indictment against the hospital management has been framed by the editor of *Mrs. Bull*, which is not in the least warranted by the facts, and which could not have been made by anyone with medical knowledge.

We have no desire to minimise the importance attaching to the treatment of patients at our voluntary hospitals; we do not suggest for a moment, even, that it is not the business of lay papers to inquire into all complaints emanating from patients, particularly if those complaints have been disregarded by those responsible for the conduct of the hospital in question; and lastly, there is an urgency about an appeal made on behalf of little children which we recognise, for little children cannot help themselves. But there is another side to the matter. It is, to our mind, absolutely necessary that those who take upon themselves the responsibility of criticising the work of a great hospital should fit themselves for the task by acquiring the necessary knowledge. The extreme frequency of vaginitis among urban children of the lower orders is absolutely unknown to the lay public—how should it be otherwise?—and the author of the article in *Mrs. Bull* was not informed on this point. Every female child on becoming a candidate for admission to the Great Ormond-street Children's Hospital is rigorously examined because of this frequency, and because of the great infectiousness of the condition those with vaginitis are almost invariably rejected. But vaginitis has an incubation period, and no inconsiderable one; indeed, it may be as long as three weeks; so that the fact that a child is admitted apparently free from the condition does not clear the hospital from the risk of taking into the general wards a highly dangerous little patient. All this is perfectly well known to medical men and, of course, to the authorities of the Great Ormond-street Children's Hospital, who have an elaborate routine of observation and isolation to prevent the spread of this disease, when it is discovered, within the hospital walls. Into all hospitals and institutions cases of vaginitis associated with the gonococcus are occasionally introduced in the incubation stage, or with such completely slight symptoms that they escape observation, and whenever this happens a chance of the spread of the infection is very great. The wonder, indeed, is not that an occasional slight outbreak should occur, but that, especially in children's hospitals, the authorities should

be able to keep the infection under so well. Dr. EMMETT HOLT, the well-known professor of diseases of children at the College of Physicians and Surgeons of New York, in his admirable text-book on the "Diseases of Infancy and Childhood," discussing the exact situation we are now considering, points out that in institutions for the treatment of children's diseases the gonococcus vaginitis once introduced, unless the patient is quarantined, will spread until entire wards or dormitories are infected, and a local epidemic may be set up which will last for months. All this is common knowledge to medical men and hospital authorities; had it been known to the editor of *Mrs. Bull* an article which might have had an evil effect upon the working of an admirable charity would surely not have been written.

A word about the "dirty heads" of the two patients whose cases form the reason of these remarks. More than three-quarters of the little patients who enter the wards of the Great Ormond-street Children's Hospital have "dirty heads"—that is to say, they harbour pediculi capitis. A uniform treatment is adopted which is almost always successful. In the case of patient A she had a dirty head when admitted and a clean head when sent home. She remained at home from June 1st to June 28th, and when she was readmitted she had pediculi capitis, which the nurses at the hospital proceeded to deal with. In the case of patient B, stated by *Mrs. Bull* to have been sent home with a "dirty head," our contemporary appears to have been misinformed, for not only when the child was sent out on March 17th was her head clean, but it was still clean when she was readmitted on March 24th. We have seen the hospital records. Here again we are sure that the strictures would not have appeared if the facts had been in the possession of the writer in *Mrs. Bull*, who was probably unaware of the extent to which pediculosis capitis is present among the *clientèle* of a children's hospital. Having looked carefully into the charges brought against Great Ormond-street Children's Hospital by our contemporary, which amount to charges of ignorance, supineness, and callousness, we have come to the conclusion that none of the accusations would have been formulated by a writer who understood the pathology of the conditions in question, who realised the enormous difficulties which the authorities of all hospitals have to contend with in preventing the spread of these conditions, or who knew the solicitude and success with which the medical and nursing staffs of the assailed institution have combated their troublesome infectiousness.

Contract Practice in Germany and Government Intervention.

IN the annual Consular Report upon Berlin, made by Mr. H. J. BRUCE of the British Embassy in that city, the difficult position which arose recently in Germany out of the relations between the medical men attending sick clubs and managers of the clubs receives prominence under the heading of strikes and lock-outs. The fact that the Government intervened in the dispute, and the attitude of the Minister of the Interior towards the medical practitioners who sought to maintain the dignity of their profession and their right to settle their own business arrangements, are instructive in view of the prominence given recently by the report of the Royal Commission on the Poor-laws to proposals for future developments in the nature of State-recognised contract practice in Great Britain and Ireland. We do not anticipate that in this country the interference of a central or local authority would be attempted upon lines possible in Germany. In that country governmental and official intervention in matters of all degrees of importance, and in those which affect both individuals and classes of individuals, are a recognised feature in the social economy of the nation, so that more can be attempted without exciting remonstrance or rousing resistance than with us. The members of a scientific profession, however, occupy a position of some strength, because the demand for their services as healers renders them more independent of public support than those whose services can be dispensed with or replaced by the work of others. Consequently, in Germany, the medical profession, although its action in its essential features hardly amounted to a strike, was able by combination to take up a strong position and to secure recognition for its views. We may ask the question here, how far the spirit of subordination to discipline and to organisation, which the German people have acquired by long usage, may have aided the medical profession in presenting a firm and united front when at length it ranged itself in opposition to authority.

The Consular Report referred to states with regard to the origin of the dispute that "a local disagreement which had been proceeding at Cologne for some time between the management of the sick clubs and the medical men of the town was followed by a general resistance on the part of the medical men to the new Governmental regulations regarding the insurance of workmen. Contracts had been concluded in 1904 between the management of the Cologne sick clubs and the doctors which were valid up to Jan. 31st, 1909." Under these agreements the members were allowed to select their own medical attendants from those who had undertaken to treat the clubs at prices fixed by their contracts. The managers of the sick clubs professed to have discovered that in order to attract patients medical men prescribed unnecessarily large quantities of food, as well as of what we should term medical extras and medicines, with the result that the expenditure on these had risen from 37 marks per head in 1903 to 57 marks in 1909. Naturally, this growth in the cost of medical treatment, to whatever cause it may have been due, necessitated increased subscriptions, and to avoid these the club authorities refused to renew the old contracts, proposing for the future a return to their previous arrangement of employing medical men paid by salaries. This change of policy, indeed, they proceeded to put into force, with the result that after negotiations which proved ineffectual the German medical union at Cologne passed a resolution refusing to treat members of the Cologne sick clubs. Shortly after this the Minister of the Interior made a speech in the Reichstag, which, although it made no direct reference to Cologne, was clearly intended as an allusion to the situation there, and in which he said, "We are face to face here with a very serious state of affairs which shows to what the coalition principle, when exaggerated, can lead. To boycott a sick or dying man, and this is what it may come to, is a social reaction of

the worst kind, and I believe that a large number of German doctors are opposed to it. But they are impeded by the fetters of coalition and the pressure exercised by the medical courts of honour. These evils, like other evils resulting from coalition, must be suppressed." To this the medical union of Leipsic, with a membership of 95 per cent. of the German medical profession, made a firm and spirited reply, declining dictation as to their conduct, and maintaining their ground.

The position taken up by the German medical men with regard to the sick clubs was as follows. That all medical men should be permitted to attend members of sick clubs after entering upon agreements to that effect, which were to be drawn up by representatives of the medical profession and of the clubs. That committees should be established, consisting of medical men and representatives of the clubs in equal proportions, to which all disputes should be submitted. That committees or courts similarly composed should be established for purposes of conciliation and arbitration. That free medical treatment should only be granted in cases where the recipient's yearly income might be proved to be below a certain figure, fixed at 2000 marks. That there should be no legal interference with the rights of medical men to combine for their own protection. It will be seen that the attitude of the medical profession in Germany was entirely dignified and proper in the circumstances. It was taken up in order to resist the sweating of the medical profession by club practice at salaries avowedly adopted in order to effect economy at the expense of the medical men. All who engaged in the struggle, many of whom no doubt were not personally interested in it, deserve full sympathy from their professional brethren in this country. The cause of the original difficulty, the supposed tendency of medical men to bid against one another for practice by prescribing in a manner likely to please rather than to cure their patients, is interesting in view of proposals to allow the choice of medical men made by the majority of the Royal Commission on the Poor-laws. As a matter of comment it may be observed that any charge of such conduct as that alleged at Cologne could not possibly be dealt with properly by club managers only. In such cases a medical committee, not a joint one of medical men and laymen, would be the most efficient tribunal, and certainly would not be one likely to deal with undue leniency with a proved case of the serious nature referred to.

Annotations.

"Ne quid nimis."

THE FOUNDER OF THE RED CROSS.

THE death of that noble philanthropist and consummate organiser, M. Henri Dunant of Geneva, revives a controversy which had been regarded as closed—a controversy arising out of the questions, "Who was the real originator of the neutralisation of the army medical service and of the wounded in time of war?" Was it M. Henri Dunant, or was he simply the "elaborator" of a conception due to another? Professor Andrea Ceccherelli of Parma, while conceding all just praise to the Swiss author of the "Souvenir de Solferino," the memorable book that described for the world of 60 years ago the horrors of the battle-field and the sadly insufficient organisation for minimising the same, writes to the leading Roman journal: "As an Italian, who has no wish to detract from the merit of Enrico Dunant, I feel it my duty to recall (to my compatriots at least) that the 'Founder of the Red Cross' was the Senator, Professor Ferdinando Palasciano." A Palasciano prize, it seems, was instituted in commemoration of the services of its "hero and eponymus," and, as reporter of the conditions and circumstances of its bestowal, Professor Ceccherelli reminds the public that in 1885 the prize was conferred by the "Società Italiana di Chirurgia" (the Italian Society of Surgery) on Gaetano Mazzini for his documentary demonstration that the "conception and founding of the Red Cross" belongs to Ferdinando Palasciano, whose beneficent work dates from an incident in the late "forties" of last century, from the conflict, in fact, between the forces of King "Bomba" and the insurgent patriots of Sicily. The controversy appears to us about as idle as it is invidious, and has its analogue in many other controversies turning on the claim to priority of this or that innovator, inventor, or discoverer. As science progresses, and as "truth," in the words of the philosopher, "emerges from the illumination of many minds on many points," ideas and generalisations tend to become more and more "of the common stock," and their first realisation or conception, on the part of independent workers in the same field, to become more and more simultaneous. Witness the discovery of the planet Neptune—claimed, and with equal plausibility, for an English, a French, and a German astronomer. The discovery was, so to speak, in the air, and if it had not been made by any of these distinguished mathematicians it must have been made by another in the immediate future. The brotherhood, or in the Italian phrase, the "fratellanza," of science is too feelingly persuaded of what it owes to coöperation and to combined endeavour, to insist overmuch on the contribution of the individual, and claims to priority, inspired too often by personal *amour propre* or by racial vanity, seem ungraciously obtrusive when the innovation in question affects the common interests of mankind—interests in which the importance of the special originator might well, without effacing itself, retire into the second line.

PRIMARY ACIDOSIS.

IN another column we publish an interesting case of primary acidosis recorded by Dr. Sidney Bontor. For the symptoms which were noted we refer our readers to the original paper. As Dr. Bontor remarks, the diagnosis was difficult. It was evidently a toxæmia and appeared to rest between uræmia, an intestinal infection, and acidosis. The urine gave no definite reaction until 13 days from the onset of the illness, then diacetic acid was found to be present and the condition was shown to be one of acid intoxication. Among the circumstances in which marked acidosis arises are conditions which especially affect glycogenesis, such as removal of the pancreas, poisoning with carbonic acid, poisoning with phloridzin, exclusive feeding on animal fats, and, of course, severe cases of diabetes. In these conditions there is great deficiency of carbohydrates, and there is excessive transference of fat from the tissues to the liver, and the acidosis is excessive. None of these conditions appear to have prevailed, as Dr. Bontor said the patient was a small eater, and he suggests that her store of glycogen was always small; on the other hand, the small amount of food taken does not indicate an excessive indulgence in fat, and, indeed, he says that she was always pale and had a very small amount of adipose tissue. Nevertheless, his theory of the production of the acidosis is probably a sound one. There was a distinct history of chill, and Dr. Bontor believes that this so

interfered with the digestive processes that an intestinal toxæmia was induced, and subsequently the liver cells were so damaged by their work in dealing with the resulting toxins that they were incapable of performing their normal function of transforming the carbohydrates into glycogen. It is thus possible that the patient's store of glycogen became exhausted during the first few days of her illness. In spite of the severe symptoms produced, the patient recovered. Dr. Bontor states that it is probably the first recorded instance of recovery after a severe primary acid-intoxication.

THE FIRST SPANISH INTERNATIONAL CONGRESS ON TUBERCULOSIS.

THIS Congress was held at Barcelona from Oct. 16th to 22nd of this year. Amongst the articles communicated to the Congress were the following: The Educational Rôle of the Anti-tuberculosis Dispensary, by Dr. S. Bernheim and Dr. Louis Dienpart. The authors commented on the great advantages that had accrued from the work of the dispensaries which had been established throughout France for the care of patients suffering from tuberculosis, and the education which had been given to the families of these patients as to the "methods for preventing the spread of the disease." Dr. S. Bernheim and Dr. P. Barbier communicated a paper on Zomotherapy in the Treatment of Tuberculous Conditions. They stated that in conditions such as tuberculosis, when the digestive functions were often feeble, it was necessary to give flesh food in the most concentrated and easily digestible form. All fibres must be removed from the meat and the juice alone should be employed. Several clinicians had stated that they had obtained the best results from the juice of horseflesh, which was rich in hæmoglobin, in proteids, and in glycogen. Dr. Bernheim and Dr. Henri Parmentier extolled the value of open-air schools; and Dr. Hervé read a paper on the necessity of treating delicate children by means of open air and carefully regulated discipline as to their daily life.

THE BLOOD PRESSURE IN AVIATORS.

THE wonderful triumphs of the new art of aviation have directed attention to the mechanics of the aeroplane, but the equally new problem of the physiological effects upon the aviator seems to have attracted little notice. The rapid ascent to great altitudes exposes the body to conditions different from any terrestrial ones. Mountain climbing offers some analogy, but it differs in the fact that the transition from the high atmospheric pressure of the sea-level to a low pressure takes place much more slowly. In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of Sept. 25th Professor R. Moulinier has reported some interesting observations on the blood pressure of aviators who have ascended to high altitudes. On alighting after ascending to a height of 1200 to 2000 metres the aviator presents cyanosis of the extremities, probably from the low temperature of the high regions of the atmosphere. Often there is congestion of the conjunctivæ. The pulse is slightly accelerated, but there is no palpitation, arrhythmia, or epistaxis. There is often slight and transient headache and tinnitus aurium. Sometimes there is a tendency to sleep, and this may be felt even during flight. After the flight the blood pressure is always increased. In one aviator at 5.30 P.M., before flight, the constant blood pressure in the radial artery was found with Pachon's sphygmometer to be 9 centimetres of mercury and the maximum pressure to be 18 centimetres; the pulse was 70. At 6 P.M., after a flight of 25 minutes, during which at the twentieth minute he reached the height of 1100 metres, the constant pressure was 12 centimetres of mercury and the maximum pressure 19 centimetres; the pulse was 80. This increase in pressure is all the more remarkable as the aviators were athletes in full training. The rise was less marked in aviators who were fatigued. These showed palpitation of the heart and marked acceleration of the pulse (108). In one case troublesome tachycardia, symptomatic of functional insufficiency of the heart, and vertiginous movements, were observed in an aviator who, after a flight of an hour, had reached the height of 1000 metres. No rise in blood pressure was found in aviators who flew at low altitudes, such as 100 to 150 metres. As to the cause of the rise in blood pressure, Professor Moulinier puts forward the hypothesis that it is due to the sudden descent to earth in four or five minutes from a height of 1000 to 2000 metres which was attained in 20 to 25 minutes. At a height of 2000 metres the atmospheric pressure is 591 millimetres of mercury, at the sea level 760 millimetres. In the short time of the descent the circulatory system had not time to become adapted to the change of pressure. He therefore advises aviators to descend more slowly. He also points out the dangerous fatigue to which flight at high altitudes exposes the circulatory apparatus by provoking increased and irregular activity of the heart and vessels. A sound heart and supple arteries are absolutely necessary to an aviator. The list of distressing fatalities to aviators has become comparatively long in a very short time. The accidents are always attributed to some mechanical cause—some breakdown in the machine or unexpected current of air. No doubt this is usually true, but it seems to us quite possible that in some cases the breakdown may have been in the human machine, which is exposed to a new and peculiar stress, both physical and psychical. It is curious that this point does not seem to have received attention.

"ITALIA INFELIX."

ITALY has need of all the consolation she can derive from her gift, her "fatal gift," of beauty. Scarcely does she begin to recover from one visitation when she seems well-nigh crushed under yet another, which imposes fresh demands on her reserve of recuperative power till this, marvellous as it is, shrinks to within vanishing point. In the spring of the present year the whole Brianza region was devastated by a cyclone of transatlantic origin and in the same season the Irpinia—the Samnium of antiquity—was convulsed from centre to circumference by one of the earthquakes apparently periodic in the southern part of the peninsula. The summer brought an invasion of cholera, which, besides inflicting loss of life and paralysis of industry, agricultural and mercantile, has bequeathed a "scare" to the season which looks wistfully for the "paying guest"; and now, when the country is endeavouring by much outlay of official energy and administrative largess to keep the malady at bay—if not, indeed, to drive it from her shores—she is again the victim of atmospheric disturbances, exploding in "nubifragi" (or cloud-bursts) which have swept the Ischian island of its hotels, its houses, and its inhabitants, and flooded the Neapolitan Riviera with water in such volume and with such violence as to bury farmsteads under débris and to submerge whole tenements with their inmates in its seaward course. It is but cold comfort to the regions so disastrously visited that the work of salvage and relief, strenuously carried out by the King and his ministers, reinforcing communal and municipal intervention, is minimising the damage done and the misery left behind. More than merely "remedial measures," however well-inspired or effectively administered, are required to exorcise that feeling of

insecurity, that vague sense of impending calamity, which has now become an *idée fixe* in the superstitious south, hardening into hopelessness and stimulating that migratory spirit which is robbing it yearly of its manhood by overseas colonisation. Well did Pasquale Villari, man of letters, philanthropist, and statesman, appeal to his compatriots through the leading journals the other day to concentrate their best thought, energy, and resource on the rehabilitation of the Two Sicilies, if these are not to weigh on them like an incubus, impeding national development, perverting growth intellectual and moral, and sullying the credit of the Italian name. When a whole urban quarter or an entire countryside in the cholera-visited south rises in revolt against the officers, medical and sanitary, who are risking their lives to cure the suffering and to protect the temporarily immune; when the police and the military have to intervene to save the devoted practitioner from being stoned to death in the discharge of his duty, surely this implies a superstition, a benighted obsession, only to be explained by the lack of education which still keeps some 70 per cent. of the proletariat "analfabeti"! Confronted by a social stratum so little removed from the savage, how vain it is to expect confidence in the measures taken to adapt house construction (for example) to the unstable soil, to second the crusade against endemic disease like pellagra or malaria, to work in sympathetic concert with the initiative of Government for the rehabilitation of the soil, for the work of re-afforesting, for the "bonifiche," as they are called, which would remunerate the husbandman's labour as certainly as sanitation would improve his health or as well-chosen building-sites would make his tenement secure. The charity which begins at home must in Italy find expression in an "instauratio à fundamentis," or rehabilitation of the submerged masses, so as to evolve an intelligent, industrious, and contented citizenship, as the primary condition of social and national health. Not till then can she emerge from her present attitude of waiting upon Providence or anticipating aid from without—aid too often deflected from its purpose or its object by malversation on the part of distributors who have come to look on a visitation like the last as a "local asset" to be utilised in any way except in that of relieving the sufferer.

VINCENT'S ANGINA.

WE have on previous occasions referred to the peculiar form of sore-throat which is called after the French writer Vincent, who first described it in 1898, and have suggested that it is seldom recognised in this country, though it must frequently come under observation and be mistaken for diphtheria. These facts are shown in a paper published in the *British Journal of Children's Diseases* by Dr. J. D. Rolleston and based on 32 cases observed in the Grove Hospital. During the years 1905–09 3266 cases of diphtheria were admitted into the hospital and 610 cases were sent in under the certificate of diphtheria, but other diseases were found. In these were 30 cases of Vincent's angina. Its frequency was 0·9 per cent. of all cases of sore-throat and 4·9 per cent. in non-diphtheritic angina. Vincent found that it occurred in 2·2 per cent. of all cases of angina, but his patients were confined to soldiers between the ages of 20 and 25 years. At the Grove Hospital 14 cases occurred in the first quinquennium, 13 in the second, four in the third, and one in the fourth. Vincent's angina may be defined as a faucial lesion, usually unilateral, characterised by deep ulceration of the tonsil and adjacent structures, a peculiar fœtor, enlargement of the corresponding lymphatic glands, and associated with the symbiosis of the two organisms, a fusiform bacillus and a spirillum. It is customary to distinguish two forms, an ulcerative and a membranous or diphtheroid, but in Dr. Rolleston's experience the ulcerative is only a later stage of the diphtheroid. The slough which covers the ulcer may so closely simulate diphtheritic membrane that even after considerable experience diphtheria may be diagnosed, especially as the characteristic fœtor is often absent in the early stage. Thus 10 cases were diagnosed as diphtheria on admission, and antitoxin was injected, but no diphtheria bacilli were subsequently found. Nasal discharge, which is so frequently an initial sign of diphtheria, occurred in 14 cases. The resemblance to severe diphtheria was increased in five cases by the occurrence of faucial œdema. Adenitis, usually confined to one side, was sometimes considerable, but there was never anything resembling the "proconsular" neck of toxic diphtheria. In every case the inflammation resolved. Suppurative adenitis, as Vincent has pointed out, is unknown. The fœtor of Vincent's angina, though characteristic and quite different from that of malignant diphtheria, may mislead those who have had no experience of the former disease. Disproportion between the severity of the local and general symptoms is one of the most striking characters of Vincent's angina. In most of the cases the constitutional disturbances were slight and lasted only during the pyrexial period, which usually was brief. In 5 cases the temperature was normal throughout; in 10 it ranged between 99° and 100° F., and in only 4 did it rise above 102°, the highest reading being 103·8°. Compared with diphtheria, Vincent's angina is protracted. In diphtheria the throat becomes clean a few days after the injection of antitoxin; in Vincent's angina healing usually takes much longer. In the 32 cases the average period was 18 days. As to treatment, in most cases it is sufficient to swab the affected part night and morning with tincture of iodine, as recommended by Vincent. If the fœtor is very penetrating the throat may be syringed with a solution of chlorate of potassium and myrrh. In one case in which the ulceration advanced in spite of these measures the application of powdered methylene blue to the ulcers on two successive days was followed by rapid healing.

PRINCES TO THE RESCUE.

Prince Francis of Teck, it is well known, had intended to devote his time and energy to building up an adequate annual subscription and donation list for the Middlesex Hospital. Had he lived undoubtedly his efforts would have been crowned with success if we may judge by the rapidity with which he secured the sum of £20,000 to pay off a three years' deficiency in the running of the charity. His death has caused a loss which it will be hard to replace, and his name will always be associated with the Middlesex Hospital, not only as a most popular chairman of the weekly board, but as one who cared for the whole welfare of the institution Fitting is it, therefore, that the memory of him should be preserved by putting into operation those plans in aid of the Middlesex Hospital which he had so much at heart. In order to carry out this intention the Duke of Teck has consented to become a vice-president of the hospital, and Prince Alexander of Teck has been willing to succeed his brother as chairman of the weekly board. In a letter which he has written to the press, Prince Alexander expresses public feeling when he says that no more appropriate tribute could be paid to the memory of Prince Francis than the establishment of an endowment fund which would produce £7000 a year, the amount by which the normal expenditure exceeds the annual income Their Majesties the King and Queen have

already signified their approval of the scheme by sending handsome subscriptions to the fund, and their example will doubtless be followed in spirit and deed by numerous donors.

OPTICIANS AND SPECTACLES FOR LONDON CHILDREN.

AT the request of a deputation from the Worshipful Company of Spectacle Makers and the British Optical Association the Education Committee of the London County Council has considered the wording of a paragraph in the recently issued "Health Hints to Parents," in which parents were advised that spectacles should be worn only when prescribed by a medical man, and should never be obtained from an optician or "eyesight specialist" unless so prescribed. A subcommittee stated that it was convinced it was not possible, without grave risk of error, to test the vision of school children without the administration of a drug which opticians, by the terms of their diploma, were forbidden to use. The Council, therefore, should advise parents to consult a doctor in respect of defect of vision in their children. At the same time the pamphlet should be so modified as to remove any suggestion which might be taken as a reflection upon opticians. The paragraph as amended reads: "The children may require spectacles, but these should be worn only when prescribed by a doctor. The children's eyes should never be tested by opticians or eyesight specialists, as these do not use the necessary drugs."

ELECTRIC CURRENTS AND MICRO-ORGANISMS.

IT is some years now since the St. George's Hospital Reports were published, the last complete volume having appeared in 1879. These were essentially clinical in character, and it has not been found feasible or advisable to revive the reports in their original form. But the Reports have been revived in somewhat different guise, the new issue consisting of accounts of the work now being carried on in the clinical and research laboratories of the hospital. The volume is under the editorship of Dr. Charles Slater, director of these laboratories, and some of the articles therein have already been published in THE LANCET and elsewhere. The one article from Dr. Slater's pen has, we believe, not appeared before. It gives the results of experiments which he made to ascertain the effect of disruptive discharges and high-tension and high-frequency electrical currents on micro-organisms. In making the numerous experiments that have been necessary, the aim has been entirely to eliminate the indirect effects of the currents employed, such as electrolytic action, heating, effects of light, and other similar agents, so that the direct influence of the current would be the only factor of any significance. The various bacteria were cultivated in U-shaped tubes to facilitate the application of electricity; other experiments were made with cultures introduced into raw beef, so as more nearly to simulate the conditions of ordinary electrical treatment. Many other modifications were carried out on dead media, and at the end of the report we have the experiments made on guinea-pigs. In all cases the results were negative. While perhaps unsatisfactory in one sense, the ultimate finding is of great importance, as it meets the uncertainty that exists in the minds of many who are more or less interested in electrical treatment. It proves conclusively that any deleterious effects on bacteria that have followed an electrical application are due to the by-products and not to the thing itself. If we imagine a number of individuals bathing in a large pond or tank to which electrodes are fitted, one at each end, and a strong current passed through (yet not so strong as to heat the water uncomfortably) it is inconceivable that any one of the individuals would intercept enough of the total current to do any harm or to feel other than a mild and possibly pleasant stimulation. This, we think, very nearly represents the experiments at St. George's Hospital as applied to human beings, and we see how our efforts to ascertain the effects of electricity, *per se*, are limited to small doses, or more correctly, low current densities. At the same time the results obtained by Dr. Slater are very significant, and we are glad to have an authoritative pronouncement on the subject, based upon careful work. The form of high-frequency application known as diathermy opens up a new phase of electrical treatment, and on account of the high current density available without electrolytic disturbance similar experiments might be carried out with it. But here, again, the current density will be limited by the heating effect, as was shown by Dr. Nagelschmidt at the Royal Society of Medicine on Oct. 21st last, when he showed how egg albumin was coagulated in a few seconds.

THE RELATION OF THE ACID-FAST TUBERCLE BACILLUS TO OTHER FORMS OF BACTERIAL LIFE.

AT the Ninth International Conference on Tuberculosis, recently held at Munich, Dr. Stephen J. Maher (Connecticut, U.S.A.) read a paper on the above subject. He first pointed out that the young growth of tubercle bacilli, human, bovine, or avian, on glycerine-broth, glycerine-agar, or glycerine-broth-potato, are consistently acid-fast and stain entire, and are of a uniform size. As the bacillary scum on the surface of the glycerine-broth in air-tight flasks grows old and heavy, and perhaps a shade darker, smears will disclose the fact that many individual bacilli have become abnormally long and have taken on a filamentous appearance. Later, perhaps at the end of six months, some bacilli will disclose a beaded or granular content, and some will have lost, in part or entirely, their resistance to the acid. With the ordinary Ziehl-Neelsen staining many bacilli will appear blue or unstained. But these changes in the bacilli composing the scum will be slight as compared with those undergone by the bacilli that from time to time have fallen or have been shaken to the bottom of the flask. No change will be noticed in the gross appearance of these heaps, but the microscope will promptly show that they contain a large proportion of bacilli that have lost their acid resistance. Dr. Maher then described in detail his experiments on tubercle bacilli which have been cultivated for long periods on glycerine-potato. He states that the several bacterial forms that he has derived from old cultures of tubercle bacilli do not digest milk or change its reaction to litmus, and that most of them preserve some of the acid-fast property of the tubercle bacillus, but at the same time he claims that culturable bacterial forms other than tubercle bacilli can grow from cultures of old tubercle bacilli. From the researches he has carried out he has formed certain "tentative deductions" which he expresses in the form of questions as follows: 1. Is not the acid-fast tubercle bacillus simply a most highly specialised acid-fast bacillus that has acquired the faculty of resisting the lytic power of the animal cell? And, like all other acid-fast bacilli, was it not derived originally from a non-acid-fast bacillus? 2. Does not the hope for the infected animal lie not in killing the invader outright but in depriving him of his acid-fast armour and weapons? 3. Does not the great sensitiveness of the tubercle bacillus to change of environment *in vitro* afford a key to the solution of nature's cures of tuberculous animals? 4. When the infected animal is cured by change and fresh air is it not because in the new environment the tubercle bacillus has difficulty in perfecting its acid-fast development and therefore grows non-acid-fast or poorly acid-fast, or breaks up into cocci, which may or may not win the next battle with the

cells? ..... 5. Is not all the literature concerning the organisms of the secondary invasion or of mixed infection in tuberculous areas a huge blunder because of its failure to recognise the fact that the so-called secondary invaders are practically always derivatives of the struggling acid-fast tubercle bacillus? Dr. Maher hopes that these points will receive attention at the next meeting of the Conference, and it would be desirable that the organising body should take his suggestion seriously into consideration. Some of the questions raised will probably be answered in the affirmative; others, especially the one in which he refers to mixed infections, will give rise to much discussion, for the results obtained by other observers directly contradict the deductions at which he has apparently arrived.

MEDICAL INSPECTION AND AFTER.

Messrs. Cornish Brothers (Birmingham) have just published an interesting pamphlet by Miss M. C. Matheson, warden of the Birmingham Woman's Settlement, on medical inspection and the ways and methods adopted by various localities in following it up. Miss Matheson deals chiefly with Birmingham's experience, but her conclusions have a general interest. The work of investigation into the matter in Birmingham was undertaken by a small committee consisting of members of the Birmingham Charity Organisation Society and the Woman's Settlement. The committee is impressed with "the absolute necessity of some system of following up the medical inspection," and suggests that the Charity Organisation Society should either establish a network of subcommittees or that the education committee of the town should organise the subcommittees as school managers. The committee further reports that the facilities for treatment of general, ear, throat, eye, and skin cases are inadequate and proposes the appointment of a school oculist. It is interesting to note the continual pressure of facts forcing all sections of opinion toward the provision of some special treatment for school children after medical inspection. There seems very little doubt that the existing machinery of medical treatment will prove insufficient for the new demands in almost all localities and will have to be supplemented by what will be in fact, under whatever name, school clinics. The Birmingham suggestions, even were it possible they could be adopted, would involve the employment of a small army of voluntary officials "who, while throwing themselves into their duties with zeal and enthusiasm, will also submit themselves to the discipline of study, system, and coöperation." London's experience, at any rate, goes to show that such an army will be impossible to recruit. The London Care Committees have apparently broken down. Excellent as Miss Matheson's pamphlet is, and useful as are some of the suggestions, it is impossible to read it without being convinced of the magnitude of the administrative problem medical inspection opens up, and convinced, too, that we are by no means on the road to its solution. If the problem of Birmingham be difficult, how much more so that of London and the great industrial regions of Lancashire and Yorkshire. London has great difficulty in any attempt to solve the treatment problem and even, as the recent sharp letter of the Board of Education shows (see p. 1364), in facing the mere inspection problem. The hospital treatment system in London may be said to have largely failed, it is cumbrous in practice and ineffective in action, while the attempt of the London County Council to concentrate its inspectors on the districts served by hospitals with whom arrangements for treatment had been made was one of the facts that led to the "selection of schools" to which the Board of Education objects. Even routine inspection is difficult in London, adequate treatment will be no easier, the teachers object to the hospital plan because of its inefficiency, and voluntary workers are only spasmodically available. The way out is not clear, and it seems unfortunate that in such circumstances the Board of Education should insist so rigidly on the carrying out of its routine arrangements for inspection of the special age groups to the detriment of freedom of experiment. The Board is no doubt right in insisting on an increase in the number of members of the inspecting staff, but this is a change that was automatically taking place under the London County Council scheme. But the Board of Education insists on stereotyping its scheme before it has been adequately tested by experience. The goodwill of the London County Council in the matter is shown by the arrangements it had made for medical treatment by the hospitals, insufficient as these arrangements are now shown to be, and by the carefully formulated plan for gradually increasing the medical staff. The matter in a nutshell is that the London County Council has been told to cease its attempt to build up a medical inspection scheme gradually and to adopt the plan of the Board of Education. It is much to be hoped that under all the difficulties it has to face the London County Council will boldly tackle the question of treatment, without which the mere inspection will be of only secondary importance.

THE STATE FEEDING OF SCHOOL CHILDREN.

THE question of the feeding of school children excited much controversy during the passage of the Education (Provision of Meals) Act, 1906, and many were opposed to placing the feeding of children on the rates, being firmly convinced that the step was one which would never be revoked and one which would be disastrous to the best interests of the community. The success of many a measure may be judged from the diminishing necessity for its continuance, and in this connexion evidence from Brighton is interesting. The education authority there was one of the first to apply for sanction to spend money out of the rates to feed ill-nourished children, and so satisfactory has been the system of feeding that according to the canteen committee, "it is practically impossible for any child to be attending school physically unfit, through lack of food, to take advantage of the education provided." Experience has shown that one canteen has been sufficient to meet the requirements of the committee, whose work for the summer period April 20th to July 27th is as follows, the figures in parentheses referring to the summer period of 1909:—

Approximate number of nominations received	400
Total number of individual children who received free meals	321 (357)
Percentage of number of children who received free meals to number of children on rolls of public elementary schools	1·7 (1·9)
Highest number granted free meals during any one week	253 (289)
Lowest number granted free meals during any one week	220 (250)
Total number of free meals granted	14,288 (14,259)

The figures show a decrease in every particular save in the total number of meals, and this is accounted for by the fact that owing to the very cold spring the summer canteen opened a fortnight earlier than in the preceding year. When the canteens were first opened in 1908 the highest number of children fed during any one week in the summer was 320; the following year this figure dropped to 289, and now to 253. Another satisfactory feature is the growing endeavour on the part of parents to do something towards paying for the meals which their children receive, for 349 meals were supplied during the period under notice to children who brought a penny to lessen the cost. This figure is an increase of 185 over that for 1909. Every care is taken to guard against imposition, and special note is made of children who

are recommended for free meals by the school medical officer and whose home circumstances do not justify the meals being given free. The names of such children are entered on what is called a watching list. There are at Brighton no fewer than 18,000 children on the rolls, and the report of the canteen committee is very gratifying and its work deserving of the highest praise.

CORONERSHIPS FOR THE CENTRAL DISTRICTS OF LONDON AND MIDDLESEX.

THE death of Dr. G. Danford Thomas led to vacancies in the coronerships of the central districts of London and Middlesex, both of which appointments he held. At its meeting on Oct. 27th the Middlesex County Council had under consideration the appointment of a coroner for the Central District of Middlesex. The district comprises Finchley, Friern Barnet, Hendon, Hornsey, and part of South Mimms. The office was filled by the election of Mr. George Cohen, M.B., C.M. Edin., barrister-at-law. The appointment for the Central Metropolitan District was in the hands of the London County Council, who at its meeting on Nov. 1st received the report of the Public Control Committee of the Council. This committee, guided by the recommendation of the Departmental Committee on Coroners, submitted to the Council the names of three candidates, two of whom held medical and legal qualifications. The third candidate, Mr. Walter Schröder, who was without either of these qualifications, had had a very large experience of coroner's work. The Council did not consider itself bound by the Departmental Committee's recommendation and appointed Mr. Walter Schröder, who received a large majority of the votes. He was congratulated by the chairman and took the oath of office.

THE PATHOGENY AND TREATMENT OF MIGRAINE.

IN the *Revue Neurologique* of Sept. 15th will be found a suggestive article by Dr. Parhon of Bucharest on the vexed question of the pathogeny of migraine and on its treatment. The causal connexion of *some* of the migraines with defective function of one or other of the internal secretory glands is more than a mere hypothesis. Hertoghe was one of the first to demonstrate a relation between periodic headache and chronic benign hypothyroidism. Many sufferers from migraine show symptoms of defective thyroid function. Richard has published an instructive case in which periodic attacks of migraine followed the successful removal of a voluminous goitre. It is a curious fact, according to Bouchard, that in 1000 cases of migraine urticaria was noted 48 times, while in a series of 1000 cases of other diseases it was only noted once. The writer quotes a similar relation in his own experience and emphasises the value of thyroid treatment in urticaria, hence the possibility of the thyroid origin of some migraines is again suggested. Further, uterine affections, dysmenorrhœa, paludism, asthma, hæmorrhoids, glycosuria —to name but a few—are conditions not infrequently associated with migraine, and many observers have recorded cases of these where the function of the thyroid gland was impaired. The treatment of migraine (*pace* Dr. Parhon, it is preferable to say "some migraines") by thyroid opotherapy has been eminently successful. It is well recognised that during pregnancy periodic attacks of migraine may diminish or cease, and it appears justifiable to associate the fact with physiological hypertrophy of the thyroid. On the other hand, Dr. Parhon relates the case of a patient with migraine, whose headaches disappeared when symptoms of the development of Graves's disease manifested themselves. He also narrates in detail two cases of migraine successfully treated by the exhibition of thyroid substance. The second of these is noteworthy for the definite amelioration of severe symptoms. It is difficult to say exactly what the nature of the thyroid impairment may be. Probably it is a matter rather of hypo- than of hyper-thyroidism. The mechanism of the production of migraine through thyroid insufficiency is equally uncertain. Dr. Parhon is inclined to believe that, on the analogy of urticaria, the migraine depends on defective calcium metabolism. The frequent disappearance of migraine after the menopause is coincident with the restoration of thyroid equilibrium as a result of the cessation of the disturbing phenomena of the catamenia, pregnancy, and lactation.

THE AUTUMNAL TINT.

THE process of nutrition arrested in the world of foliage is probably responsible for the beautiful and varied colours which delight the eye in the autumn. Physiology and chemistry are concerned in the development of the leaf; they are concerned also in its demise, and they conspire to make the end æsthetic. The loss of vitality is sad, but it affords some consolation that chemistry finds an artistic conclusion in the production of a glorious series of yellow, red, and browns. Chlorophyll gently metamorphoses into erythrophyll or chrysophyll by a mysterious molecular re-arrangement dependent upon the supplies of energy being cut off. It is possible that the withdrawal of the vital supplies is a process of conservation. The tree stops expending its energy and stores it up for future contingencies, that it may tide itself over the winter or keep locked up an energy which is reserved to send forth buds again in the succeeding spring. Carefully conducted analysis has shown that while with many species the amount of nitrogenous material remains permanent in the summer, the quantity steadily diminishes as the season of autumn approaches, in which case the leaves grow red, while with other species when the chlorophyll fails the amount of nitrogenous material may be much the same in autumn as in summer, in which case the leaves go brown. To the former category belong the wild cherry, rowan, birch, and elder, and sometimes the oak and beech; and to the latter the sycamore, hazel, elm, and alder. In an interesting note in the *Chemical News* (Oct. 28th) upon the subject Dr. P. Q. Keegan regards the physiological causes of these differences as being due to the vegetation in the one set of cases terminating earlier than in other cases, and hence the organic principles already formed and apt for chemical transformations remain permanent, having, so to speak, nothing more to do and tend to accumulate relatively to the other constituents. In the declining vitality of the foliar organ incident to the approach of autumn the energy necessary to the sustenance of albuminoid activity is, Dr. Keegan considers, not forthcoming. On the other hand, in those trees where the vegetation is exhausted the albuminoids remain stored up as a sort of reserve with no stimulus to transform or de-assimilate into chromogen. The study is a most interesting one, and clearly bears analogies to colour phenomena in the human subject.

THE King has graciously consented to become Patron of the West London Hospital, Hammersmith-road, W., in succession to his late father, King Edward VII. The late Duchess of Teck always took a warm interest in this institution, where there is a ward (the Mary Adelaide) bearing her name. His Majesty has also graciously consented to become Patron of Epsom College, in succession to his late father, King Edward VII.

THE Drapers' Company has offered to erect a physiological

laboratory at Cambridge at a cost not exceeding £22,000, the plans to be approved by the Company, and the site and maintenance to be provided by the University. More judicious and timely generosity it would be hard to find.

THE next session of the General Council of Medical Education and Registration will begin on Tuesday, Nov. 22nd, when Sir Donald MacAlister, the President, will take the chair at 2 P.M.

THE annual dinner of the Royal Society of Medicine will be held under the presidency of Sir Henry Morris, President of the society, on Tuesday, Nov. 29th, at the Freemasons' Tavern, Great Queen-street.

THE Master and Wardens of the Society of Apothecaries of London have issued invitations to dinner at their hall to meet the Lord Mayor and Sheriffs, on Tuesday, Nov. 22nd.

THE MOTOR EXHIBITION AT OLYMPIA, LONDON.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

THE ninth International Motor Exhibition organised by the Society of Motor Manufacturers and Traders, opens its doors at Olympia to-day (Friday, Nov. 4th). As I have done on former occasions, I visited the scene of glittering brass and electric lights on the previous day, when there was less bewilderment, and I was able to try to find the cream among the rich milk that the show certainly provides for those in search of a motor-car. As the general public were not present, I was able without any discomfort to inspect pretty well every stand, and in the following very brief report mention is made of certain stands that ought to be inspected by all considering the purchase of a car. The space at my disposal does not allow of mention of many exhibits that I should like to write about, but so far as I could I noted in my wandering inspection everything most likely to appeal to a medical man.

The Adams Manufacturing Co., Limited, of Bedford, who introduced their single cylinder 10 h.p. car some five years ago, are on Stand No. 40, where the popular one-lunger is shown as a chassis and with a torpedo type body. They also show a 16 h.p. four-cylinder 85 mm. by 120 mm. This can be supplied with the Adams' planetary gear, or a sliding type gearbox can be fitted. With the former there is a smooth passage from one speed to the next without the possibility of a failure, and it is operated by a pedal or hand lever working in a gate. Many little refinements are included with this model—a self-starter, operated from the driving seat, front wheel brakes, a compressed air tank for inflating tyres or blowing horn or whistle, and abundant locker room.

The Alldays and Onions Engineering Co., Limited, of Birmingham, who are at Stand 59, inform me that their past season cars have proved so satisfactory that no radical alterations have been found necessary in their new models. They are specialising chiefly in a four-cylinder 14–18 h.p. model. The valves and tappets are enclosed by easily detachable covers, lubrication is by the mechanical force feed system, and the magneto is fitted at the forward end of the engine. Bevel pinions have now been substituted in the differential for the spur wheels formerly employed, and these cars are certainly worthy of consideration.

The Anglo-American Motor Car Company, Limited, of Heddon-street, Regent-street, London, exhibit on Stand No. 86 one of the latest American importations—the Overland Car. The 15–20 h.p. has a pressed steel frame and live axle drive, cooling by thermo-syphon, Bosch ignition, and Dunlop tyres. As the price (£220) for a two-seater will undoubtedly appeal to medical motorists I trust shortly to be able to give an account of a road trial on this car.

Messrs. Argylls, Limited, of Alexandria, near Glasgow, whose cars have always been favourites with medical men, are on Stand No. 34, and their new 12 h.p. model is sure to maintain their reputation. The engine is a four-cylinder, cast *en bloc*, bore 72 mm., stroke 120 mm., valves of large diameter, all on one side, and enclosed by an easily detached cover. Ignition is by high tension Bosch, driven by a cross shaft. All oil ducts are cast as part of the base chamber, and the lubrication is by a gear pump. A tell-tale of special design on the dash enables the driver to either see or feel that the oil is being circulated, the latter possibility being extremely useful for night work. The carburetter is a Zenith. Cooling is by thermo-syphon, with fan and honeycomb radiator. The whole suspension system is fitted with grease injectors, thus making lubrication certain. Two independent internal expansion brakes, operated by a hand lever, act on the back hubs, while the foot pedal brakes act on the front hubs. The clutch is of the multiple disc type running in oil. A range of four forward speeds and a reverse is provided, and all the gears are controlled by one lever working in a gate quadrant. The propeller shaft has two universal joints and is encased in a steel torque tube, the front end of which is fitted with a large spherical joint, which takes the torque thrust and at the same time forms a cover for the universal joint. The final drive is by a worm, and the floating shaft is fitted throughout with ball bearings. This chassis is well adapted for either a two-seater, double phaeton, torpedo, or coupé landaulette body.

Stand No. 70, where the New Arrol Johnston Co. of Paisley show their 15·9 h.p. car, should on no account be passed. These cars have forced feed lubrication to all the engine bearings, power unit and transmission gear *en bloc*, thermo-syphon cooling, metal-to-metal clutch, and valve tappet gear accessible but enclosed in a dustproof casing.

The Austin Motor Company of Northfield, near Birmingham, are on Stand No. 65. Their 15 h.p. town carriage has the driver's seat placed centrally and has the engine beneath, thus permitting a short wheel base, which is an advantage for town work.

A fleet of cars by the Belsize Motors Company, of Clayton, Manchester, on Stand No. 83, especially the 14–16 h.p. car, should be looked at, for I understand that several medical men have had good service out of this make, and the price is reasonable. The cylinders are 90 mm. by 120 mm. and cast in pairs, the clutch is metal-to-metal, th $_{e}$ carburetter is a White and Poppe, and the ignition is by Bosch magneto. Riley detachable wheels can be supplied.

On Stand No. 19 Messrs. Bentall and Co., of Heybridge, Maldon, Essex, show five examples of their 16–20 h.p. four-cylinder autocars. The chief points of this "all-British" car are single unit gearbox, propeller shaft, and back axle. All four brakes act on the road wheels direct, are compensating, and actuated by independent mechanism. The clutch is fibre-to-metal and runs in oil, and the gearbox has three-point suspension.

Messrs. Brown Brothers, Limited, of Great Eastern-street, London, show on Stand No. 48 a 20–22 four-cylinder, with a torpedo body, a 20 h.p. landaulette, and a four-cylinder 10–12 h.p., this latter both as a four and a two-seater. These 10–12 h.p. cars seem eminently suitable for professional use, and I trust at an early date to describe them fully. Messrs. Brown Brothers have also on Stand No. 212 a most useful set of accessories. The new Gabriel horn, which has a four-note chord of exceptional carrying power, is especially useful for cars with a strong exhaust. The Roper safety control is an ingenious contrivance for enabling the occupant of a car to fix the highest speed at which the car shall be driven. Various autoclipse lamps, which have recently been improved though the price has been reduced, jacks, motor stethoscopes, tyre covers, brake linings, and other odds and ends that are so dear to the heart of the enthusiastic motorist are also shown.

Cadillac motors shown by Messrs. F. S. Bennett, of Shaftesbury-avenue, London, have always been favourite American productions, and their stand, No. 99, is sure to be thronged, especially as a chassis, stripped to show the working of the mechanism and electrically driven, is on view.

The Clement Motor Company, Limited, of Leicester-square, London, through indifferent luck at the ballot, were unable to secure a really satisfactory stand in the main hall, and thus have taken up their position at Stand No. 136 in the annexe, where will be found four finished cars and a polished chassis. Their cars differ very little from the 1910 type, with the exception of the 14–16 h.p., where the stroke of the engine has been increased from 102 mm. to 120 mm. Ball bearings are employed throughout the transmission gear. High tension Bosch magneto only is fitted, and in lieu of a supplementary

ignition they advise those who desire a stand-by in this matter to carry a ready-timed spare magneto. The upholstery and inside fittings of these cars are worthy of special attention.

The Continental Tyre and Rubber Co., Limited, of Clerkenwell-road, London, E.C., are at Stand No. 308, where their square tread, three ribbed, and red-black and chrome leather non-skid tyres are shown. The leather type of non-skid is recommended for town work, and the red-black for country.

The Cowey Engineering Co., Limited, of Kew Gardens, S.W., show on Stand No. 146 their patent Cowey suspension, which was described in THE LANCET of June 4th, 1910, p. 1566. The car shown has been especially made for and built with this pneumatic suspension.

The Daimler Co. of London are on Stand No. 54, where they have four cars fitted with the Silent Knight engine. The 12 h.p. is a new production and has a four-cylinder engine 69 mm. by 114 mm., with a worm final drive. The Knight engine has made many claims since it appeared two years ago. I do not know if this motor gives more power, but it is certainly very silent, and yet I should not, I think, even yet throw over the faithful poppet valves. Poppet valves have done good work and will, I am sure, continue to do so. Still many have written asking my advice on this question, and now that a small Knight is on the market I hope some day to give my experience of a run in one.

Last year the exhibition of Messrs. A. Darracq and Co., Limited, of Walnut Tree Walk, Kennington, was undoubtedly of interest to the profession on account of the introduction of a 14-16 car at 225 guineas. The display this year at Stand 37 is equally worthy of close inspection. Half-a-dozen models are mounted—a 10 h.p. four-cylinder two-seater, three 15 h.p., and a landaulette on a 22 h.p. chassis. The 15 takes the place of last year's highly satisfactory 14-16. The price complete with standard body is £275, and although this is an advance on the figure asked for the 1910 car, the more expensive design of the chassis, better-class body, and high side doors to the driver's seat make it even better value than last season's model. One of the chasses is fitted with a torpedo body of the firm's own design, price £295; another, with a two-seated body, has been produced especially for the profession, and with hood, wind-screen, and a commodious tool-box at the back and high side doors to the driver's seat is excellent value for £295. The four-cylinder 10 h.p. should be a sweet-running car. The cylinders are 68 mm. by 120 mm., which means a £1 11*s.* 6*d.* tax. The price with a standard body is £210.

The Deasy Motor Car Company, Limited, of Coventry, are on Stand No. 66, and are showing their new small four-cylinder model, which has a worm-drive back axle, gate change-speed, and detachable wire wheels, and a most comfortable two-seated landaulette body.

The De Dion Bouton Company, of Great Marlborough-street, W., have several models on Stand No. 36. There are few departures from the 1910 type, except that a new two-cylinder engine has been brought out, and that in some there is an increased length of stroke in proportion to the bore. On the lower-powered cars a new plate clutch is fitted. All the engines now have high-tension magneto ignition.

The most striking object on the stand of Messrs. S. F. Edge, Limited, Stand No. 39, is a replica of the Napier car that gained the Grand Prix at the Brussels International Exhibition, and which was subsequently destroyed by fire. It is a cabriolet, and therefore can be used as a entirely open or a completely shut car. I noted many novel features in detail of finish, notably some beautiful panel-work in the interior and some very comfortable moveable seats. The attraction to doctors will be the 15 h.p. chassis, highly polished all over, and exquisitely finished in every detail by hand. The special points are forced lubrication through a hollow crank-shaft, wide and efficient road-springs, accessible magneto, with advance and retard actuated by a lever on the steering wheel, water circulation by thermo-syphon, and a multiple plate clutch, two-jet carburetter, and live axle with a worm drive. A model de luxe landaulette on a 15 h.p. chassis, painted jet-black with fine lines in white, and white wheels picked out in black, is also worthy of notice.

At Stand 252 the Electric and Ordnance Accessories Company of Aston Manor show a standard car front wheel fitted with Timken bearings. This is mounted on a cast-iron base and revolves by means of an electric motor. A weight represents the end thrust, and the arrangement illustrates the capacity of this bearing to withstand side-thrust loads. The rollers and surfaces against which they bear are adjustable on account of their taper shape, which certainly is an advantage over the ordinary and non-adjustable bearing.

Messrs. J. C. Fuller and Son, of Old Ford, E., devote a large portion of Stand No. 258 in the gallery to illustrating their devices for car lighting. Their system of wiring, which they term "wireless," acts by enclosing the insulated conductor in a metal sheath, which later serves as a return for the current. This method obviates unsightly loose wires, and the sheath is so small in diameter as to be almost imperceptible. The mechanical act of placing the lamp on the bracket makes electrical contact, thus avoiding the one trouble of the generality of electrical lighting—the connecting and disconnecting of wires. Their dynamo is very small and compact, and can be driven by either direct gear or a V belt. The standard machine is wound for an output of nine volts and will work two head-lights, two side, tail, and interior lamps. When the E M F drops below normal the circuit is automatically broken, and in addition it is interrupted by mechanical means depending upon the rate of rotation of the armature.

Every motorist has an interest in cutting down that big item of expense to motorists, the upkeep of tyres, and all will be interested with the exhibit at Stand No. 208, where Messrs. Harvey Frost and Co., Limited, of 39, Great Eastern-street, show their various vulcanising plants for repairing covers and tubes. They also show a new all-rubber motor tyre tube with an absolutely flush and therefore frictionless join. This tube has a flush valve seating and the valve stem is fitted with the "Warland" dust and rust proof cap, which is so easily attached and detached.

The London Motor Garage Company, Limited, of Wardour-street, W., on Stand No. 82, show various types of the Charron car. This motor was fully described in THE LANCET of July 2nd, 1910, and the mechanical details of 1911 differ but slightly from those previously given. This firm are prepared to enter into a contract for the maintenance of their cars and so to relieve the owner of all the worry incidental to the care and management of car and driver.

Messrs. Markt and Co., of City-road, E.C., have on Stand No. 232 a variety of the Jones speedometers; also their little giant wheel-pulling device, which is most useful for drawing off stubborn wheels.

At Stand No. 30 Messrs. Morgan and Co., Limited, of Long Acre and Old Bond-street, have a fine collection of Adler cars, including the 12 and 15 h.p. The former was described in THE LANCET of Feb. 19th, 1910, and there cannot be two opinions as to the attractiveness of these models, which, moreover, can be purchased with confidence that every one will yield excellent service.

The Milnes-Daimler Company, of Tottenham Court-road, have, on Stand No. 143, a fine show of the latest Mercedes models, including a live-axle 15 h.p. chassis, which has a double cone leather clutch, high-tension ignition, and a four-cylinder 70 mm. by 120 mm. engine. Their 40 h.p. has a "Mercedes Knight" engine.

Messrs. Minerva Motors, of Holborn-viaduct, on Stand No. 61, show their 16 h.p. landaulette, which has a silent Knight engine, a strengthened back axle, cardan shaft with universal joints at both ends, and the shaft is completely enclosed in a pressed steel casing, which serves as a central torque tube. Bosch dual ignition takes the place of the single ignition that was used on last year's type.

The New Engine Company, of Acton, W., are on Stand No. 24. Their special feature is "No bonnet." The machinery is arranged in the centre of the chassis, thus allowing greater body space; in fact, the body is carried in front of the rear axle, which results in extraordinary smoothness, even over the roughest roads.

Messrs. Panhard and Levassor, of Acton, W., present on Stand No. 43 a fine set of models, all painted the well-known Panhard green. One body is by Vincent of Reading, another by Messrs. Barker, and both are strikingly handsome in appearance and well finished. On the 25 h.p. a silent Knight engine is fitted, and on the 12–15 h.p. the ordinary and certainly excellent poppet valve motor supplies the power. Messrs. Panhard now employ the popular live axle instead of transmission by chains.

The Phœnix Motors, of Caledonian-road, N., are on Stand

No. 138. Like all keen manufacturers, this firm have carefully considered the question of alterations in their models for 1911, and as a result of the past success they have decided that no amendments are called for. Their feature is a central Hans Renold chain for transmission of the power from the gearbox to the live axle, which has the advantage of flexibility. A two-cylinder Minerva 90 mm. by 100 mm. engine is fitted on the 8–10 h.p., and a 102 mm. by 115 mm. on the 10–12 h.p.

On Stand No. 46 Messrs. Renault Frères, of Newman-street, W., show four cars and two chassis, and these all undoubtedly display the excellence of workmanship for which this firm is noted. The bodies, too, are on a par with the engines, especially a limousine landaulette by Hooper, and an ideal sedan coupé by Rothschild. The latter is fitted on their two-cylinder 8 h.p., and is a very suitable car for a professional man.

At Stand No. 171 in the gallery the Rotax Accessories Company, of Great Eastern street, E.C., show the Rotax-Leitner car lighting system, also wind screens suitable for torpedo bodies, and an extensive range of mascots, tyre pumps, horns, and tool kits.

The Star Motor Works, of Wolverhampton, are on Stand No. 64. These makers have for years catered for the medical profession, and the five cars which they have on view this year are excellent examples of their productions. The 12 h.p. has an engine 80 mm. by 120 mm. stroke, and there is a special universal joint between the clutch and gearbox, which latter has now four speeds forward, with direct drive on the top.

The Sunbeam Motor Car Company, of Wolverhampton, are represented on Stand No. 69 by a couple of chassis and three complete cars. The car that will appeal to the profession is certainly the 12–16 h.p., which has four cylinders 80 mm. by 120 mm., worm drive, with the transmission tipped, so as to make it one straight line. Four forward speeds are fitted, with the direct drive on the top speed.

The Swift Motor Company, of Coventry, are on Stand No. 44. The popular 7 h.p. single cylinder, which was described in THE LANCET of July 23rd, 1910, has now an entirely new engine fitted, and the main bearings are of phosphor bronze. These are attached to the upper portion of the crank case, the lower half merely acting as an oil reservoir. The ignition is by magneto with advance and retard lever.

Messrs. C. A. Vandervell and Co., of Acton Vale, W., show their variable speed dynamo car lighting system, in which, at a very low cost, a constant voltage is secured over an astonishingly wide range of speed without the slightest mechanical complication. Their smallest dynamo, costing some £7 7*s.*, weighs about 16 pounds, is driven off the engine, and will give 5 ampères at 4 or 6 volts, which is sufficient to keep an accumulator charged and to light the usual side, tail, and interior lamps of a car. A full range of C.A.V. lamps, ignition coils, magnetos, and electrical fitments are also shown.

The feature of the exhibition of the Valveless Car Company, of Prince's-street, W., is a sectional engine so cut away that the valveless system can be easily seen.

The Vulcan Motor and Engineering Company, of Southport, have on Stand No. 87 three samples of their 15·9 h.p. cars, one of which, fitted with high side doors, buttoned upholstering, black leather hood, and folding wind screen, is specially designed for a doctor's use. On this car the crank chamber, flywheel pit, and gearbox are all bolted up together and three point suspended. The cylinders, 80 mm. by 120 mm., are cast in pairs. Cooling is by thermo-syphon, and the water jackets round the valve chambers are of unusually generous dimensions. The crank shaft has three long bearings, and the connecting rod ends have Walker-Hanna patent bearings, which permit of new ones being put in without any expert assistance. The inlet valves are paired for each cylinder, and the inlet passages for the mixture are cast between them, thus permitting warming of the gases on their way. The clutch is of the leather-faced cone type. Lubrication is by a rotary oil pump, with a tell-tale on the dash board. Ignition is by a Bosch magneto driven off the distribution gear. Three speeds forward and a reverse are provided, and the final drive is by an overhead worm through a flexible joint.

Messrs. Warwick Wright, of High-street, Marylebone, W., are on Stand No. 74. Their 12–14 model, which will chiefly appeal to the profession, has an engine 75 mm. bore and 110 mm. stroke. The features are the usual metallurgique clutch, spring drive, pressure fed petrol, four-speed gearbox, and control levers on the steering column. All their coach work, it will be noticed, is by Vanden Plas, and is really a revelation of artistic sense, and gives the maximum amount of room with luxury of upholstery.

The Wolseley Tool and Motor Car Company, of Birmingham, have always been favourites with the profession, and their present models 12-16 and 16-20 h.p. cars are sure to attract attention, especially from old clients, all of whom had such good work out of their early and excellent little 6 h.p. cars. The 12-16 model was described in THE LANCET of Sept. 11th, 1909, but since then several alterations in engine details have been made. The valves are of larger diameter, and the carburetter is now more accessible. The starting handle is carried on the engine in a manner similar to the larger Wolseley cars. The change-speed and brake levers have been altered to render them more suitable for bodies with closed-in fronts, and the reverse lock has been replaced by a push button on the change-speed lever. Both front and rear wheels are fitted with Timken roller bearings, which are held in a cage, adjustable independently of the hub, to facilitate removal of the wheels. A torque bar has been added, the springs have been lengthened, and the frame is built narrow in front to give a good steering lock. The four cylinders have a bore of 79 mm and a stroke of 114 mm., thus bringing the car into the (to doctors) £2 2*s.* tax class. The transmission of power to the live axle is by worm gearing. The car shown has a rotonde phaeton body, with a scuttle dash and high driver's doors, and with a Cape hood and a wind screen constitutes an ideal car, certainly worthy the consideration of prospective purchasers. The 16–20 h.p. is shown in chassis form, and is made in two wheel bases. The short wheel base is long enough for the usual touring body and the longer one answers for a closed carriage. The rear axle is worm-driven, and to reduce the angle of the propeller shaft universal joints the engine and gearbox are inclined to the main frame. As on the smaller model, the valve area has been increased and the starting handle is on the engine. The carburetter is carried high and arranged for pressure feed, the air pump for the pressure being combined with the oil pump. The clutch has an adjustable spring and is of the metal-to-metal multiple disc kind. The gearbox provides four speeds forward and one reverse, the direct drive being on the top.

Other cars and accessories, as well as the general features of the cars, will be considered next week.

(To be continued.)

THE MEDICAL INSPECTION OF LONDON SCHOOL CHILDREN.

Letter from the Board of Education.

THE Education Committee of the London County Council on Oct. 26th had before it a letter from the Board of Education dated Oct. 7th, 1910, with reference to the provision in the metropolis for the medical inspection of school children. The Board stated that the work of the inspecting officers was generally satisfactory and thorough, but on considering the facts reported by its medical department the Board was unable to avoid the conclusion that the work of the staff of inspecting officers was not adequately organised and controlled, and that there was little or none of that effective supervision or guidance in the primary work of medical inspection which was absolutely necessary if a large staff of part-time officers was to be employed. Moreover, the arrangements for following up the defects and ailments disclosed by inspection to the stage of treatment and for securing the maximum advantage from the Council's own expenditure on treatment had been ineffective and unsatisfactory. The visits of the Board's officers fully confirmed the view expressed in a former letter to the Council that the arrangements for inspection in London did not comply with the requirements of the Education (Administrative Provisions) Act, 1907, and of the Code for 1909–10.

On a review of all the facts, the Board could not resist the conclusion that by adopting or acquiescing in a scheme of medical inspection widely different from the schemes which had approved themselves to other great education authorities the Council had not only placed itself in direct conflict with the Code and the Act, but had failed to lay a satisfactory foundation for the work of amelioration it had in

view. If the Council was to avoid waste, confusion, and embarrassment in this matter, a radical change in the organisation of medical inspection was required. The Board has no means of judging whether the proposals recommended to be adopted as from Jan. 1st, 1911,[1] would insure, in fact, the satisfactory organisation and direction of the work of medical inspection and the other branches of the school medical service of London. But as regards the proposal to increase the staff of school doctors it appeared to the Board that the number of inspecting officers recommended could not by any possibility suffice to carry out within the year the number of inspections required by the Board's minute made under section 13 of the Act of 1907 on June 25th last, modifying article 58 (b) of the Code for 1909, unless they were to be available for the whole of the 12 months of that year. The proposals before the Council, however, were recommended for adoption, not as from the reopening of the schools after the summer holidays, but as from Jan. 1st next. In these circumstances it was imperative that consideration should be given by the Council at once to the question of supplementing the scheme now before it, and such further medical assistance should be provided as might be necessary to secure that the requirements of the Board's minute of June 25th should have been fully and not partially satisfied in all public elementary schools during the current year—i.e., the year ending July 31st, 1911—and that compliance with those requirements should not be confined to the later months only of that year.

In view of the urgency and importance of the matter the Board asked for an early reply, giving precise information as to the changes to be brought in operation during the present autumn to remedy the many and grave defects in the present system of medical inspection in the metropolis, and to bring to an end the Council's long-continued failure to carry out the requirements of Parliament in this respect, so gravely affecting, as it did, the health of the rising generation in London, for which the Council was responsible.

Draft Reply approved by the Education Committee.

The subcommittee recommended that the clerk be directed to reply to the Board of Education explaining that the summer recess was the cause of the delay in replying to the Board's letter of May 17th, and setting forth the increases in the staff of school doctors and the central medical staff agreed upon by the Education Committee in July last.[2] The suggested letter proceeded: "In view of the long recess it was found impossible to bring this scheme to the Council before Oct. 25th, and the Council on Nov. 1st approved without modification the scheme which had been informally brought before the notice of the Board of Education." (It will be observed that the subcommittee took for granted the approval by the Council of the recommendations of the Education Committee discussed this week.) The letter concluded: "The Council gathers that the Board does not suggest that the number of officers proposed by the scheme referred to will not be sufficient under normal circumstances to carry out the requirements of the Act and of the Code for 1909–10, as well as to devote attention to the other phases of medical inspection which are not required by the Act or Code but on which the Council lays great stress. It is suggested, however, by the Board's letter that owing to the date on which the last of the staff will be appointed it will not be possible to carry out before July 31st, 1911, the requirements of the Code for the current educational year. In this connexion it should be stated that the Council has devoted great attention to this aspect of the question, and the Board may rest assured that the requirements of the Code as at present understood will be fully carried out within the current educational year."

The draft letter was approved and forwarded to the Council, which discussed on Nov. 1st the letter from the Board of Education and the scheme reported in THE LANCET of August 6th last, submitted by the Education Committee at the same time.

Discussion at the London County Council.

At the meeting of the Council on Nov. 1st Mr. HOBSON criticised in detail the Education Committee's estimate of the number of inspections which could be made in 12 months by 100 quarter-time medical officers. It was proposed to inspect the children at three periods: on admission, and between the ages 8 and 9, and 12 and 13. He congratulated the committee on being in advance in that respect of the Board of Education whose proposals were too narrow. The number of children in London requiring inspection was estimated at 220,000, and to inspect these a staff of 100 quarter-time medical officers was to be provided. Taking 100 quarter-time medical officers as equivalent to 30 full-time men (the quarter-time officers did rather more than a quarter of a week's work) and deducting one-fifth, or six medical officers, whose time would be taken up with other work—urgent cases, re-examinations, &c.—there remained 24 medical officers to do the work—not in a year, but before July 31st next. The Board of Education, in one of the gravest and most considered rebukes ever passed upon an education authority by a Government department, gave 7000 cases as the absolute maximum one medical man working full time could examine in a year, and the experience of Bradford and Surrey, after allowance had been made for difference of conditions, appeared to confirm this view. The figure 7000 multiplied by 24, the number of full-time school medical officers to which the Council's staff was equivalent, gave 168,000, leaving a deficit of over 50,000. Until Jan. 1st, 1911, only 72 quarter-time medical officers would be at work, so that this figure was an under-statement.

Mr. FRANK SMITH urged that the Council was not adequately following up medical inspection with treatment. By using the hospitals for giving treatment the Council was really doing a disservice to those institutions, because people were arguing that as hospitals were being subsidised out of the rates there was no need to give voluntary subscriptions. Thanks to the intervention of the Council poor people were being deprived of the free access to the hospitals they formerly enjoyed. Mr. Smith mentioned a case in which a parent on his own initiative sent his child to an ophthalmic hospital. The child was asked what school it attended, and a few days later the father received from the Care Committee a notice calling upon him to pay the cost of treatment on penalty of a fine or a term of imprisonment.

Mr. CYRIL JACKSON, chairman of the Education Committee, asked the Council to rely on the opinion of Dr. Kerr, who was the pioneer of medical inspection in this country, that the proposed staff was adequate. If the work did get behind, some of the inspection which the Board did not absolutely require the Council to carry out might be dropped temporarily, or a few extra medical officers could be appointed. As to quarter-time as compared with full-time medical officers, the quarter-time system was tried on the advice of the medical officer, who was of opinion that it enabled the Council to obtain the services of a large number of very able young medical men who could give part of their time while they were building up a practice. On the other hand, there were advantages in appointing full-time officers, and the question might be reconsidered whenever it was thought desirable.

An amendment requiring the Education Committee to submit definitely a supplementary estimate in order that the number of school medical officers might be increased was rejected by 62 votes to 45.

The Council then approved the scheme for extending medical inspection in the way proposed by the Education Committee, and for the rearrangement of the medical staff as follows: Three additional full-time assistant medical officers to be appointed, two as from Jan. 1st, 1911, and one as from Sept. 1st, 1911, each at a salary of £500 a year. From Sept. 1st, 1911, the present scheme for the appointment of part-time school medical officers to be abolished and to be superseded by the following scheme: 100 school medical officers to be employed, each at a salary of £120 a year, including travelling expenses; 25 medical officers to retire as from August 31st, 1912, and thereafter 25 yearly; the vacancies thus caused to be filled by the appointment of 25 medical officers yearly.

A decision regarding the letter from the Board of Education was postponed after an interesting debate which showed that the Council was perfectly prepared to revise its present system of medical inspection.

---

[1] THE LANCET, August 6th, 1910, p. 424.
[2] Ibid.

HARVEIAN SOCIETY OF LONDON.—The annual dinner of this society will take place at the Café Royal, at 7 P.M., on Nov. 10th. Dr. M. Handfield-Jones, the President, will occupy the chair.

INTERNATIONAL CONGRESS OF RADIOLOGY AND ELECTRICITY, BRUSSELS.

THE opening meeting of the Congress was held in the Palais des Fêtes of the Exhibition on Sept. 13th. Professor DE HEEN, the President, thanked the King and the Government for the welcome they had extended to the Congress.

International Standard of Radium and Radio-activity.

Professor E. RUTHERFORD (Manchester) read his report on the Preparation of an International Standard of Radium. For this purpose the Congress nominated a provisional international committee composed of Madame Curie, Professor Rutherford, M. Boltwood, M. Soddy, M. Eve, M. Meyer, M. Halm, M. Meyers, M. Geitel, M. Schweidler, and M. Debierne, with the addition of M. Duane and M. Dane from Madame Curie's laboratory. This committee was instructed to report to the Congress on the last day of the session.

Mr. W. DEANE BUTCHER (London) presented to the Congress the report of the Standards Committee of the Roentgen Society, and a communication from the President, Mr. C. E. S. Phillips. He drew attention to the fact that an international standard of radio-activity was of equal importance to the radiologist and to the physicist, as the basis on which to found the dosage of X rays and the calibration of Roentgen tubes and apparatus.

The following was the report of the Standards Committee to the Congress: (i.) Madame Curie will prepare a standard of pure metallic radium containing about 20 milligrammes. (ii.) When the Standards Commission shall have reimbursed Madame Curie the standard shall be under the control of the committee for comparison with secondary standards. This standard shall be kept in Paris. (iii.) National scientific laboratories may procure secondary standards which have been compared with the international standard. (iv.) Smaller secondary standards may also be prepared with the approval of the committee. (v.) The emanation of radium being much used in scientific research the committee considers it desirable to adopt a unit of quantity of the emanation. In accordance with the proposition of the Congress the international committee recommends the name of "Curie" to be given to the quantity of the emanation equivalent to one gramme of metallic radium. The quantity of emanation in equilibrium with one milligramme of radium will be one millicurie. (vi.) The committee will study the question whether a special name should be given to a smaller quantity of radium and to the emanation in equilibrium with it. (vii.) As some members of the Standards Committee were absent these propositions are only provisional. A committee consisting of physicists and physicians was constituted to prepare the question for a future congress, and to determine the date and place of the congress, and was composed as follows:—Physicists: Madame Curie, Professor Rutherford, M. Van Aubel, M. Righi, M. Exner, M. Boltwood, M. Vershaffels, M. Vien, M. de Heen, and M. Daniel. Physicians: Mr. Deane Butcher, Dr. Bergonié, Dr. Bayet, Dr. His, Dr. Lester Leonard, Dr. Ludwig, and Dr. Hauchamps.

Madame Curie read a paper on the Preparation of Metallic Radium. She made use of the method described by M. Guntz for the preparation of metallic barium. The method consisted in preparing an amalgam and driving off the mercury by distillation in an atmosphere of pure hydrogen. The amalgam was obtained by the electrolysis of a solution of pure radium chloride (atomic weight, 226·5), using a cathode of mercury and an anode of platinum and iridium. Pure metallic radium is a brilliant white metal, fusing suddenly at 700°. It alters rapidly in air, becoming black from the formation of a nitride. It blackens paper when allowed to fall on it. It decomposes water, giving an energetic effervescence and itself disappears, thus showing that the oxide is soluble in water.

Section of Biology and Medical Radiology.

Presidents of Honour: Dr. Bergonié, Mr. Deane Butcher, Dr. Lester Leonard, Dr. Schiff, Dr. His, Dr. Miura, and Dr. Decref; Dr. Leon Hanchamps was nominated secretary.

Dr GUILLEMINOT read a paper on the Action of the New Radiations on the Development of Plants. He used 20 milligrammes of radium of activity 200,000 (2 milligrammes of pure radium) at a distance of 2 centimetres for times varying from several hours to two months.—In the discussion which followed Professor SCHIFF said he had only obtained negative results.—Dr. LÖWENTHAL considered that the different rays had a different biological influence.—Professor MIURA (Tokio) considered that the injurious action of radium on the living cells depended greatly on the time of exposure and the energy of the cells.—Dr. SUDGENT (Berlin) had found that sodium mono-urate was decomposed by radium *d*—i.e., by a decomposition product of radium.—Dr. HALM (Berlin) discovered that radium *d* emits soft β rays. Sodium mono-urate was not decomposed by the α and γ rays or by the ordinary β rays. Hence we had a means of differentiating the radiations by their chemical action.—Dr. KASPARI said the experiments of Köousche showed that a stimulation of the plantule was produced by the radium radiations. His own experiments showed the same results. The difficulty was to place the exact limit where the stimulating action ceased and was replaced by a depressing action. This was also of importance in the radium treatment of malignant tumours.

Dr. HARCKMAN of Toumai read a paper on the Ionic Theory in Biology.

Madame FABRE and Dr. OSTROWSKY (Paris) read papers on the Action of Radium on Toxins, and on the Inverse Action of Radium on various Species of Microbes.—Dr. JABOIN drew attention to the different units of radium dosage used in France and Germany respectively. In France the dosage was by weight—microgrammes of radium, whereas the German dosage by electrostatic units varied with the capacity of the electroscope employed. One-hundredth of a microgramme—i.e., a hundred-millionth of a gramme of pure radium—was capable of giving a quantity of emanation with a potential of 7000 volts.—Dr. WICKHAM drew attention to some experiments which he had made on the action of radium on staphylococci. He found that radio-active solutions in extremely small doses had a retarding effect greatly in excess of that produced by the direct rays of radium. The emanation of radium appeared to exercise a special action on cultures, a result which was in accordance with the therapeutic action of the emanation obtained by injecting soluble or insoluble preparations of radium into the substance of a tumour.

Dr. D'HALLUIN (Lille) contributed papers on (*a*) Injection of the Vascular System for Stereoscopic Radiography; (*b*) the Method of the Anaglyph for Stereoscopic Reproduction of Medical Photographs. Marey, Rémy, and Contremoulin were the first to inject the veins for purposes of skiagraphy, and to show the utility of stereoscopic radiography in the illustration of anatomical and medical subjects. The author showed a marvellous series of stereoscopic clichés of the injections of the upper and lower limb, the heart, the kidney, the lungs, and the circulation of the fœtus. The material used for injection was a suspension of vermilion in essence of turpentine. (In stereoscopic observation we are met with the impossibility of showing stereoscopic pictures on the screen. To obviate this, Ducos invented the method of anaglyphs—i.e., the projection of the right stereoscopic image in red and the left in green, the composite image being viewed through spectacles furnished with red and green glasses.)

Dr. FIRSSEL (Stockholm) read a paper on Gastric Terminology from the Radiological Standpoint. The division of the stomach into the pars cardiaca and pars pylorica was only an artificial one, since the position of the angle between the two portions was very inconstant. The real division should be into the stomach proper and the antrum pylori, since these were distinct organs both functionally and morphologically. The author gave to the first of these segments the name of saccus digestorius, and to the second canalis egestorius, Digestionsack and Entleerungskanal respectively. The three regions of the stomach, cupola, body, and base, he designated by the names fornix, corpus, and fundus. He also distinguished between the pars verticalis and the pars transversalis, although these had no morphological difference.

Dr. DECREG (Madrid) read a paper on the Diagnosis of Schlatter's Disease. Roentgen diagnosis had been of the greatest service in the diseases and injuries to the bones and joints of children. It was not uncommon to mistake the retardation of the joining up of the epiphysis at the end of the humerus for a fracture or a traumatism of the elbow. Still more important was the Roentgen diagnosis of the osseous centre forming the tuberosity of the tibia. This centre, which appears late in the course of development,

had been accurately studied by radiographic means, and the deformity which often occurred as a consequence of its malformation was known in Germany by the name of Schlatter's disease. It was usually brought under our notice in young patients of from 14 to 18 years of age, and was generally the result of over-exertion at football or of "pelote" in Spain.

Dr. LEVIN and Dr. BARRET (Paris) read a paper on the Radiological Exploration of the Stomach.—Professor HIS (Berlin) said that the time necessary to empty the stomach depended on the contents of the intestines and the habits of the individual. Kulbs had shown that the stomach of a well-fed animal was emptied much more rapidly than the stomach of an animal fed only every two or three days. In human pathology we often found false dilatation due to habitual constipation and the bad habit of eating a heavy meal once a day.

Mr. HEINZ BAUER (Berlin) read a paper on the Measurement of the Hardness of a Roentgen Bulb, and showed his electrostatic electrometer for measuring the voltage between the two electrodes of an X ray tube.—In the discussion Professor BERGONIÉ alluded to a series of experiences four years ago on the use of the electrometer for the measurement of the degree of hardness of the rays emitted by an X ray tube. In his laboratory the instrument of Hartmann and Braun had been used for over a year, but had to be abandoned in consequence of the cost.

Dr. AUBOURY read a paper on the Radiography of the Small Intestine.

Dr. LESTER LEONARD (Philadelphia) read a paper on Rapid Roentgenography of the Thorax and Abdomen, and showed some beautiful stereoscopic plates of the movement of the small intestines and of the stomach.

Professor MIURA (Tokio) read a paper on the Treatment of Painful Skin Affections by Radium.—In the discussion which followed Professor SCHIFF of Vienna drew attention to the cure by radium of pruritus, the result of neurodermatitis. Radium appeared to have a specific action on the nerves of sensation.

Dr. GUDZENT (Berlin) read a paper on the Action of Radium on the Uric Acid of the Organism, in which he stated that radium emanation when introduced into the organism behaved like an indifferent gas. When introduced by inhalation, ingestion, or injection it was almost entirely eliminated in a few minutes by the lungs. A very small quantity was eliminated by the kidneys. There was no cutaneous penetration or elimination. The emanation was transported by the blood to the cells of the organism, and there set up a biological action which was due partly to the emanation itself and partly to the products of its decomposition. Radium emanation could transform urate of soda into a more soluble substance, and even break it up into ammonia and carbonic acid. This influence was exerted by radium and by one of the products of decomposition of the emanation which had the property of giving off very soft β rays. This influence of the emanation of radium had been observed in animals as well as in man. The emanation of radium had an inhibitory effect on the movements of the leucocytes, and on the inflammatory processes, and an activating effect on organic ferments, but it had no bactericidal nor antitoxic action. The stimulating effects on ferments had been observed with autolytic and diastasic ferments, as well as the ferments which preside over the metabolism of the purins. In gout, a disease of faulty metabolism, the radium emanation was of great efficacy, facilitating the elimination of uric acid. In 13 out of 14 cases of gout the uric acid in the blood had disappeared as a result of treatment with the emanation.

Dr. CHEVRIER (Paris) read a paper on the Effects, General and Local, of Small Doses of Radium. The doses consisted of from 20 to 40 microgrammes of radium.—Dr. WICKHAM stated that he had obtained good results in lupus from radio-active solutions prepared by M. Jaboin. He had obtained better results, however, from injections of the insoluble salt. In a case of cancerous nodule of the breast he injected 12 centigrammes of a preparation of radium sulphate in paraffin vaseline containing 10 microgrammes per cubic centimetre. In other cases he injected solutions of a soluble salt containing 10 microgrammes per cubic centimetre. In these cases the radio-activity ceased in about four days. Some years ago he studied elimination by the urine after injection of radio-active mercurial solutions. The elimination was at a maximum on the first and second days, and completely disappeared after four days.

Dr. FORSSELL (Stockholm) read a paper on Experience in the Radium-therapy of Cancerous Tumours. The author had treated 38 cases of cancerous tumour at the Seraphina Hospital of Stockholm. Radium had an effect similar to but more efficacious than the X rays. In most superficial cancers of the skin the two methods were alike. In cancer of the lips and mouth radium was superior to X rays. In certain cases deeper subcutaneous tumours had disappeared where X rays had but little effect. The best results were obtained with Dominici's tubes embedded in the tumour. The pain of cancerous tumours might be relieved by radium entirely or in part.

Madame Dr. FABRE (Paris) and Dr. MAX EGGER (Geneva) communicated a paper on the Effect of Radium in a Case of Multiple Sclerosis. The patient was a syphilitic, 42 years of age, with fulgurating pains, abolition of the patellar reflex, and Argyll Robertson pupils. Three radium applicators with a lead filter were placed along the spine for 24 hours with great relief of the symptoms. After two more applications there was a further regression of the symptoms.

Dr. WICKHAM and Dr. DEGRAIS (Paris) communicated a paper on the Radium Treatment of Angioma.—Dr. D'HALLUIN (Paris) bore testimony to the marvellous effects of radium in these cures. He inquired if it were safe to apply the cross fire of two or more radium applications on the forehead. He himself had no fear of any injury to the brain. In the worst cases of hæmorrhagic nævus he had never had the least trouble from bleeding, although he had feared it and warned the friends of the possibility.—Madame Dr. FABRE had irradiated the brain and spinal cord in cases of syringomyelitis and other lesions of the nervous centres without any trace of ill-effect, in one case using 4 centigrammes of a radium preparation for 24 hours. There was no danger in irradiating the nervous system with large doses of radium, provided the radiations were filtered. The lesions, if any, were not in the nerve cells, but due to hæmorrhage from destruction of the endothelium of the vessels.—Professor BÉCLÈRE (Paris) believed there was no danger to the brain either from radium or Roentgen irradiation of the scalp when properly applied. Any ill-effects would be shown rather on the cartilaginous cells of the skeleton of the face and cranium which were not yet ossified.

Dr. KERNEN and Dr. NEUMANN (Kreuznach) read papers on the Exchanges in Gout under radio-therapeutic treatment and the absorption of the radium emanation.—Professor HIS (Berlin) drew attention to the negative results which had been obtained at the medical clinic of Berlin, results entirely opposed to those of Dr. Kernen.

During the Congress the Société Belge de Radiologie, which is a very strong one both in numbers and in *personnel*, held a meeting at which Mr. Deane Butcher made a communication on Auto-Immunisation by means by X Rays and Radium.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Thursday, Oct. 27th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College: John Bright Banister, M.D. Camb.; Alexander Edward Gow, M.B. Lond., L.R.C.P.; Frederick Arthur Lucas Hammond, L.R.C.P., Major, I.M.S.; Henry Pratt Newsholme, M.B. Oxon.; Ernest Henry Shaw, L.R.C.P.; Cuthbert Allan Sprawson, M.D. Lond., L.R.C.P.

Licences to practise medicine were granted to 68 gentlemen who had passed the necessary examinations.

The PRESIDENT stated that at the celebration of the 400th anniversary of the birth of Dr. Caius, recently held at Cambridge, the President and other officials of the College were entertained at Caius College, and the hospitality there enjoyed was returned by inviting the Master and Fellows of Caius College to be present on the occasion of the Harveian oration and banquet. The President also stated that a copy of the portrait of Francis Glisson in the possession of the College had been presented to Caius College.

The PRESIDENT announced that the Jenks Scholarship had been awarded to Mr. Gerald Gibbons.

The following communications were received: 1. From the Home Office respecting an International Congress for the Amelioration of the Condition of the Blind, to be held at Cairo in February next. 2. From the Secretary of the Royal College of Surgeons of England. 3. From Dr. Herbert French, offering on behalf of the medical staff of Guy's Hospital to present to the College a portrait of Sir Samuel Wilks. The gift was accepted with acclamation, and the thanks of the College were ordered to be returned to the donors.

A report was received from Dr. Amand Routh, representative of the College at the International Congress of Obstetrics and Gynæcology held in St. Petersburg in September last.

The audited accounts of the College for the year ending Sept. 29th were laid before the Comitia and adopted.

The quarterly report of the College Finance Committee was received and adopted.

Dr. F. W. Andrewes was re-elected a member of the Executive Committee of the Imperial Cancer Research Fund, and Dr. Frederick Taylor was re-elected a member of the Committee of Management.

A report from the Committee of Management, dated Oct. 4th, 1910, was received and adopted. Amongst the matters dealt with in the report the committee recommended:

(*a*) That a candidate who has passed the first examination for the degree of B.Sc. of the University of the Cape of Good Hope with a standard of not less than 50 per cent. be exempted from the first examination of the Conjoint Board in chemistry, physics, and biology.

(*b*) That the course of laboratory instruction in public health given by an officer of the Royal Army Medical Corps in the laboratory of the Sanitary Commission, Gibraltar, be recognised for the Diploma in Public Health, provided that the officer conducting the course is in possession of a Degree or Diploma in Public Health.

(*c*) That the course of laboratory instruction in public health given at the South African College, Capetown, be recognised for the Diploma in Public Health.

(*d*) That attendance on the practice of the City Fever Hospital, Capetown, at which instruction in the methods of administration is given, be recognised for the Diploma in Public Health.

After other formal business had been transacted, the PRESIDENT dissolved the Comitia.

MEDICINE AND THE LAW.

Two Cases under the Workmen's Compensation Act.

THE efforts of the workman to obtain compensation in excess of that to which he may be entitled are well known to medical practitioners. Two recent cases in which "accidents" were held not to come within the provisions of the Act may be cited, although no point of medical interest arises in them, in order to show the nature of the claims that are made against employers, and which they, or the insurance companies, are put to expense in resisting. Both were heard in metropolitan county courts on the same day—Oct. 27th. In the first, at Whitechapel, the workman, employed as a billiard-marker and potman at a hotel, went to bed on the third floor of the building, after the hotel had been duly closed for the night. A disturbance took place in the street outside, and in order to see what was going on, and, as he alleged, in order to prevent injury to his master's property, such as might occur if windows were broken by two women whom he had ejected earlier in the evening, he leaned out of window. In doing this he overbalanced himself and fell, sustaining severe injuries. In the other case mentioned the workman was injured in a quarrel with a fellow workman. His honour Judge Emden appears to have suggested that if there had been evidence that the quarrel arose out of something connected with the employment it might be different, but he, like Judge Bacon in the first case referred to, declined to hold that injuries received as described entitled the applicant to recover compensation on the ground that they were due to accidents arising out of, and in the course of, his employment.

A County Court Judge upon Sanitary Precautions.

At the Gainsborough county court recently a debtor sought to excuse himself from compliance with an order to pay 4*s.* a month on the ground that he was out of work and could not therefore obey. Upon this the county court judge, Sir Sherston Baker, inquired why he was out of work, and received an answer to the effect that the debtor was a jobbing joiner and that members of his family had recently been ill with scarlet fever, so that for a time the sanitary authority had warned him that he would lay himself open to legal proceedings if he entered other people's houses in order to work there. The comment of Sir Sherston Baker is thus reported in the *Daily Telegraph*: "I never heard of such a thing. What right have they to stop a man working without compensating him? Look at the doctors; they go from house to house, visiting fever cases, and are not afraid of going home to their families. They go visiting all manner of sick. Take an action against them; it would serve them jolly well right." Comment upon this judicial utterance is hardly necessary, unless wonder is expressed as to whether the advice given has been followed by its recipient.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

A MEETING of the Organising Committee was held on Oct. 28th in the Royal College of Physicians of London, the President, Sir THOMAS BARLOW, being in the chair.

Letters of regret were received from the following: Dr. T. Dyke Acland, Professor H. G. Barling, Sir James Barr, Dr. Barrs, Mr. George A. Berry, P.R.C.S. Edin., Dr. J. Mitchell Bruce, Sir John Byers, Dr. P. J. Cremen, Sir Halliday Croom, Dr. H. Davy, Professor D. W. Finlay, Dr. J. Magee Finny, Sir Thomas R. Fraser, Dr. Edwin Goodall (Cardiff), Mr. J. W. B. Hodsdon, Professor James Little, Professor H. Littlejohn, Sir Donald MacAlister, Professor Dixon Mann, Professor Howard Marsh, Sir Isambard Owen, Dr. R. W. Philip, Sir G. H. Philipson, Sir Richard Douglas Powell, Mr. J. Scott Riddell, Mr. A. W. Mayo Robson, Dr. F. M. Sandwith, Professor R. Saundby, Professor T. Sinclair, Sir W. Smyly, Professor E. H. Starling, Dr. StClair Thomson, Professor W. Thorburn, and Dr. Norman Walker.

The PRESIDENT pointed out that the list of the Organising Committee was originally drawn up with a view to territorial representation only. At the meeting of the General Committee on Oct. 12th a wish was expressed, and partially carried out, that it should represent also departments of practice. In order to fulfil this wish the following additional members were nominated for election: Miss Aldrich-Blake, Dr. F. W. Andrewes, Dr. J. B. Ball, Dr. Lazarus-Barlow, Dr. J. S. Barr, Dr. E. F. Bashford, Dr. A. E. Boycott, Dr. H. G. Brooke, Dr. W. Bulloch, Mr. Arthur Cheatle, Miss Cock, Mr. Treacher Collins, Mr. A. E. Cumberbatch, Sir W. Dalby, Professor G. Dean, Professor A. F. Dixon, Mr. Dudgeon, Dr. Colcott Fox, Dr. Galloway, Dr. Garrod, Dr. Albert Gray, Dr. Dundas Grant, Professor Greenfield, Dr. de Havilland Hall, Dr. E. Hobhouse, Mr. W. H. H. Jessop, Mr. Robert Jones, Mr. Reginald Jowers, Dr. Lambert Lack, Mr. Richard Lake, Dr. Edward Law, Mr. J. B. Lawford, Lieutenant-Colonel Sir W. B. Leishman, Mr. H. Littlewood, Professor Alexander MacAlister, Dr. P. McBride, Sir John MacFadyen, Dr. C. J. Martin, Dr. W. Milligan, Dr. F. W. Mott, Dr. D. R. Paterson, Dr. F. M. Pope, Dr. J. J. Pringle, Dr. Urban Pritchard, Professor Arthur Robinson, Mrs. Scharlieb, Mr. S. G. Shattock, Professor Sherrington, Professor Lorrain Smith, Mr. Priestley Smith, Dr. G. F. Still, Dr. G. A. Sutherland, Mr. H. H. Taylor, Professor Peter Thompson, Professor W. H. Thompson, Dr. StClair Thomson, Miss Thorne, Dr. Herbert Tilley, Miss Jane Walker, Dr. Watson Williams, Professor Sims Woodhead, and Sir Almroth Wright, and these were unanimously elected with power to add to their number.

The PRESIDENT then nominated the following for election as members of the Executive Committee:—Sir A. Pearce Gould (chairman), Sir Clifford Allbutt, Sir W. Allchin, Mr. A. A. Bowlby, Sir Francis Champneys, Sir W. Church, Dr. Bertrand Dawson, Mr. Clinton Dent, Mr. R. J. Godlee, Dr. Norman Moore, Sir Malcolm Morris, Professor Osler, Dr. Pavy, Sir R. Douglas Powell, Mr. D'Arcy Power, Sir Felix Semon, Mr. Charters Symonds, Dr. Hale White, the Chairman of the Finance Committee, the Chairman of the Reception Committee, the Chairman of the Council of the British Medical Association, a member to be nominated by the Faculty of Medicine of each of the universities,

excluding Oxford and Cambridge (which are already represented), viz. :—England, Universities of Birmingham, Bristol, Durham, Leeds, Liverpool, Manchester, and Sheffield; Scotland, Universities of Aberdeen, Edinburgh, Glasgow, and St. Andrews; Ireland, University of Belfast, Trinity College, Dublin, and the National University of Ireland; and Wales, University College, Cardiff.

Sir A. PEARCE GOULD proposed, and Mr. D'ARCY POWER seconded, the addition of Mrs. Scharlieb to this committee. These members were unanimously elected, with power to add to their number.

The PRESIDENT then stated that Sir Dyce Duckworth had consented to act as the second treasurer with Mr. Makins, and he nominated the following as members of the Finance Committee: Sir Henry Morris (chairman), Dr. Herbert Spencer, Dr. Frederick Taylor, Sir Edgcombe Venning, and Mr. E. Francis White (Putney). These were unanimously elected with power to add to their number.

The PRESIDENT then nominated the following for election to the Reception Committee: Sir T. Lauder Brunton (chairman), Mr. A. E. Barker, Sir W. H. Bennett, Sir Havelock Charles, Sir Anderson Critchett, Sir Thomas Boor Crosby, Mr. Edmund Owen, Dr. Pasteur, Dr. StClair Thomson, Dr. Samuel West, and Dr. Theodore Williams, with power to add to their number.

The permanent officers of the Congress are *ex-officio* members of all committees.

The PRESIDENT then said a few words on the organisation of the various committees. The Executive Committee was intended (*a*) to manage local matters; (*b*) to act as a board of advisers to the President; and (*c*) to receive and consider reports from the Finance Committee, the Reception Committee, and the various sectional committees when appointed. It was to be understood that when the business of a section or sections was to be discussed the President of such section or sections would be summoned to the meeting of the Executive Committee. It might be necessary, in the view of any general regulations being drawn up, that all Presidents of sections should be so summoned. The Organising Committee was intended to act (*a*) when summoned as a whole as the ultimate committee of reference, and of election to appointments of presidents, vice-presidents, secretaries, and councils of sectional committees; and (*b*) to be the source from which special committees could be drawn if necessary to advise and report on matters pertaining to the organisation of the several sections.

The Organising Committee then adjourned.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

THE undermentioned Captains to be Majors (dated Oct. 28th, 1910):—John E. Hodgson, Matthew H. G. Fell, William B. Winkfield, Jonas W. Leake, John W. H. Houghton, George M. Goldsmith, Richard H. Lloyd, John M. Sloan, D S.O., Harry D. Packer, Lawrence Humphry, Arthur O. B. Wroughton, and Frank Ashe.

Lieutenant Wilfred W. Treves, from the Seconded List, is restored to the establishment (dated August 27th, 1910).

Lieutenant Charles V. Nicoll to be Captain (dated Nov. 1st, 1910).

Frederick William Lumsden to be Lieutenant (on probation) (dated Oct. 13th, 1910).

Colonel M. W. O'Keefe, from Rawal Pindi, has taken over the duties of Inspector of Medical Services at the Horse Guards, Whitehall. Lieutenant-Colonel F. W. C Jones, at present serving at Tidworth Park, has been placed under orders for the Fourth (Quetta) Division. Lieutenant-Colonel C. Birt, on return from special service at Malta, has been appointed to the Dublin District and posted to the medical charge of the Royal Infirmary, Phœnix Park. Lieutenant-Colonel B. McCreery has been appointed to the medical charge of the troops and their families at Perth. An exchange on the roster for service abroad has been sanctioned by the War Office between Lieutenant-Colonel C. W. Johnson and Lieutenant-Colonel S. G. Allen. Lieutenant-Colonel G. F. Gubbin has arrived home from Colaba, India, on leave. Major F. S. Penny has embarked for a tour of service in South China. Captain A. W. Sampey has been transferred from Colchester to Warley. Captain A. C. Adderley on the termination of his course for promotion at the Royal Army Medical College, London, has been posted for duty to Lichfield. Captain P. H. Henderson, from Portsmouth, has joined at Ibsley Camp. Captain F. E. Rowan-Robinson has been granted leave on medical certificate from Colchester. Captain R. B. Ainsworth has been appointed to Cosham from the Royal Army Medical College, London. Captain J. H. Douglass, on completion of duty at Maryborough Heath Camp, has been posted to the Dublin District. Captain A. Hopping has been appointed a Specialist in Radiography and Electrical Science to the First (Peshawar) Division of the Northern Army in India. Captain S. M. Adye-Curran, from Bere Island, has joined at Queenstown. Captain H. T. Stack, from Finner Camp, has been appointed to Belfast. Captain H. Harding, from Churn Camp, has taken up duty at Tidworth Camp. Lieutenant F. H. Somers-Gardner has been transferred to Hilsea, from Rowlands Castle. Lieutenant R. C. G. M. Kinkead, from Cork, has joined at Ballyvonare Camp. Lieutenant T. W. Stallybrass, from Netley, has been appointed to Tidworth Camp.

ROYAL ARMY MEDICAL CORPS EXAMINATION.

An examination of candidates for not less than 15 commissions in the Corps will be held on Jan. 25th, 1911, and following days. Applications to compete should be made to the Secretary, War Office, London, S.W., not later than Jan. 16th. The presence of candidates will be required in London from Jan. 23rd.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel R. H. Castor, civil surgeon of Mandalay, has been granted six months' leave on account of ill-health, with effect from the date he was relieved by Major A. Fenton. The services of Major D. H. M. Graves, Madras Presidency, have been placed at the disposal of the Home Department of the Government of India. Major E. Wilkinson has been confirmed in the appointment of Sanitary Commissioner of the Punjab. Major J. H. Hugo, agency surgeon in Bundelkhand, has been granted six weeks' privilege leave. The services of Captain H. M. Mackenzie, medical officer of health, Simla, have been placed temporarily at the disposal of the Government of Bengal. Captain J. S. Babonau has been selected for plague duty in the Punjab. Captain B. S. Mehta, assistant plague medical officer at Amritsar, has been appointed District Plague Medical Officer at Jhelum. Captain J. W. H. Babington has been appointed to the substantive medical charge of the 76th Punjabis. Captain M. J. Quirke has joined the Civil Medical Department of Madras Presidency. On return from leave Captain J. J. Robb has been detailed to act as Superintendent of the Central Jail at Vellore. Captain C. F. Weinman has been granted three months' extension of his leave by the Secretary of State for India. Captain P. S. Mills has been appointed a Specialist in Radiography and Electrical Science to the Fifth (Mhow) Division of the Southern Army, India. Captain J. A. S. Phillips has been appointed to officiate as Civil Surgeon at Jacobabad. Captain W. P. G. Williams has been posted to Madras Presidency for employment in the Jail Department, and has been appointed to the Central Jail at Coimbatore for a course of instruction. Captain W. S. Patton, of the Madras Civil Medical Department, has been placed on special deputation duty connected with investigations into the occurrence of Delhi sore. Lieutenant A. J. Lee has been appointed to the Officiating Medical Charge of the 3rd Brahmans. Lieutenant F. A. Barker has been appointed Superintendent of the Cellular and Female Jails and Civil Surgeon at Port Blair. Lieutenant G. G. Jolly has been appointed a Specialist in Radiography and Electrical Science to the Fourth (Quetta) Division of the Southern Army, India.

SPECIAL RESERVE OF OFFICERS.

THE undermentioned Lieutenants are confirmed in their rank:—Duncan Macfadyen and Charles M. Page.

William Leckie Webster to be Lieutenant (on probation) (dated Oct. 4th. 1910).

TERRITORIAL FORCE.

Royal Army Medical Corps.

4th Southern General Hospital: The appointment of Lieutenant-Colonel Charles E. Russell Rendle and of Major Henry W. Webber is antedated to Sept. 29th, 1908.

Attached to Units other than Medical Units.—Major Richard J. M. Coffin resigns his commission (dated Oct. 29th, 1910).

ARMY MEDICAL RESERVE.

The undermentioned Lieutenants to be Captains (dated Nov. 1st, 1910):—John F. Murphy, Samuel K. Adams, and Murray R. Taylor.

ROYAL ARMY MEDICAL COLLEGE.

Mr. Haldane distributed the prizes at the Royal Army Medical College, Millbank, on Oct. 29th. After paying a tribute to the building itself and the excellent equipment of the Royal Army Medical College, which was largely due to the work of his predecessor, Lord Midleton, who, as Mr. Brodrick, threw himself wholeheartedly into the work of raising the Army Medical Department to a higher standard of excellence, he, Mr. Haldane, referred to the experiments which had been made with regard to physical training and endurance, and said that we now knew exactly what the rations of the British soldier fighting under emergency conditions must be in order to sustain him in strength and health. With regard to the new clothes equipment, that was also the outcome of modern physiological science. Very great progress had been made in the reduction of disease in the army, particularly in India, and the whole work of the Army Medical Department had vastly improved in recent years. There was a time when this department did not contribute to science in any large degree, but its modern organisation gave scope for every kind of talent. He instanced the names of Sir William Leishman, Sir David Bruce, and Sir Almroth Wright in connexion with the important bacteriological work done by the Medical Department of the army, and after referring to the importance of physiological work, concluded by reminding his hearers that what was needed was exact knowledge, and if that were obtained the money spent on equipping and maintaining the college, which was one of the most important parts of the British army, would be saved over and over again. The following is a list of the prize-winners:—Lieutenant W. W. Treves, R.A.M.C., first Montefiore prize (first in military surgery), Parkes memorial prize (first in hygiene), Marshall Webb prize (military medical administration), Herbert prize for the highest aggregate; Lieutenant H. E. Shortt, I.M.S., second Montefiore prize—second in military surgery; Lieutenant R. C. Clifford, I.M.S., Fayrer memorial prize—pathology; Lieutenant C. H. H. Harold, R.A.M.C., Tulloch memorial prize (pathology), Ranald Martin prize (tropical medicine); Lieutenant R. F. Bridges, R.A.M.C., De Chaumont prize—second in hygiene. It is interesting to note that Lieutenant Treves is a nephew of Sir Frederick Treves.

DEATHS IN THE SERVICES.

Surgeon-Colonel F. H. Welch, A.M.D. (retired), at his residence, Southborough, Kent, aged 71 years. He entered the service as assistant surgeon in 1861, became surgeon in 1873, surgeon-major in 1876, brigade-surgeon in 1886, and retired with the rank of surgeon-colonel in 1895. He served in the Egyptian War of 1882 and was present at the battle of Tel-el-Kebir (medal with clasp and Khedive's star). He also served with the Nile Expedition in 1884–85. Surgeon-Colonel Welch was distinguished for his professional (medical) attainments and writings on various subjects, and won the Alexander prize medal in 1873 and again in 1882. His contributions on enteric fever, military ophthalmia, and especially on aortic and arterial disease in connexion with syphilis may be mentioned as excellent. He was a frequent contributor to THE LANCET.

THE LATE MISS FLORENCE NIGHTINGALE.

At a meeting held at Grosvenor House on Oct. 28th, under the presidency of Lord Charles Beresford, M.P., a committee was formed with the object of considering the various projects recently put forward to perpetuate the memory of the late Miss Florence Nightingale. The committee will consist of Mr. Haldane, Lord Crewe, Lord Pembroke, Lord Selborne, Lord Charles Beresford, Sir Thomas Barlow, Sir J. Dimsdale, Sir W. Treloar, Mr. H. T. Butlin, Mr. J. H. Shore Nightingale, and Miss McCaul, with power to add to their number.

At a meeting held in the Court Room at St. Thomas's Hospital on Nov. 1st it was decided that a fund for providing a memorial to Miss Florence Nightingale, O.M., should be established and that contributions should be invited from all parts of the Empire. Part of the memorial will take the form of a statue.

THE LATE HENRI DUNANT.

M. Henri Dunant, the founder of the International Red Cross Association, died recently at Heiden, in Switzerland, at the age of 82. Profoundly influenced by the work of Harriet Beecher Stowe, Florence Nightingale, and Elizabeth Fry, he organised an ambulance service to deal with the wounded at Solferino, and started the campaign at Geneva, then looked upon as utopian, which led to the formation of the Geneva Conference of 1863. In the following year 12 Powers signed the famous convention "for the amelioration of the condition of soldiers wounded on the battlefield." He received the Nobel Peace Prize in 1901.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8104 births and 4222 deaths were registered during the week ending Oct. 29th. The annual rate of mortality in these towns, which had been equal to 13·1 and 13·0 per 1000 in the two preceding weeks, was again 13·0 in the week under notice. During the first four weeks of the current quarter the death-rate in these towns averaged 13·0 per 1000. In London the death-rate during the same period, calculated on the probably over-estimated population, did not exceed 12·7 per 1000. The lowest reported annual death-rates last week in these 77 towns were 5·1 in Leyton, 5·8 in Hornsey, 7·0 in East Ham, and 7·5 in Willesden, all metropolitan suburban districts with probably over-estimated populations; the rates in the other towns ranged upwards to 18·7 in Stoke-on-Trent, 19·2 in Oldham, 21·6 in Newport (Mon.), and 23·1 in Tynemouth. In London the reported death-rate last week did not exceed 12·9 per 1000. The 4222 deaths from all causes registered in the 77 towns last week were within 9 of the number returned in the previous week, and included 425 which were referred to the principal epidemic diseases, against 504 in each of the two preceding weeks; of these 425 deaths, 184 resulted from diarrhœa, 107 from measles, 42 from diphtheria, 35 from whooping-cough, 30 from enteric fever, and 27 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·3 per 1000, against 1·6 in each of the two previous weeks. No death from any of these diseases was registered last week in East Ham, Wolverhampton, King's Norton, Ipswich, or in 9 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·1 in Preston, 3·2 in Brighton, and 3·7 in Northampton and in Tynemouth. The deaths attributed to diarrhœa in the 77 towns, which had declined in the eight preceding weeks from 527 to 296, further fell last week to 184; the highest annual rates from this cause in the 77 towns last week were 2·0 in Merthyr Tydfil and 2·1 in Warrington. The fatal cases of measles, which been 51 and 75 in the two previous weeks, further rose last week to 107, and exceeded the number returned in any week since the beginning of July; they caused the highest annual rates, 1·5 in Stockport, 1·6 in Brighton, and 2·8 in Tynemouth. The 42 deaths referred to diphtheria corresponded with the number in the previous week, and included 11 in London and its suburban districts, 3 in Norwich, and 3 in Cardiff. The fatal cases of whooping-cough, which had been 49, 47, and 37 in the three preceding weeks, further declined to 35 last week, but showed an annual rate equal to 1·6 per 1000 in Northampton. The 30 deaths referred to enteric fever exceeded by 2 the number in the previous week; 14 occurred in London and its suburban districts, and 2 both in Stoke-on-Trent and in Salford. The 27 fatal cases of scarlet fever exceeded the number in the previous week by 1, and included 9 in Liverpool, 3 in Birmingham, and 2 both in Manchester and in Walsall. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased in the ten preceding weeks from 1423 to 1792, had further risen to 1847 on Saturday last; 221 new cases of this disease were admitted to these hospitals during last week, against 245, 234, and 231 in the three preceding weeks. The 1209 deaths from all causes in London last week included 234 which were referred to pneumonia and other diseases of the

respiratory system, against 162 and 194 in the two previous weeks, and exceeded by 25 the corrected average number in the corresponding week of the five years 1905–09. The causes of 31, or 0·7 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Sheffield, West Ham, Bradford, Hull, Salford, Portsmouth, and in 50 other smaller towns; the 31 uncertified causes of death in the 77 towns included 7 in Liverpool, and 2 each in Birmingham, Grimsby, Nottingham, Burnley, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 839 births and 460 deaths were registered during the week ending Oct. 29th. The annual rate of mortality in these towns, which had been equal to 12·9 and 13·0 per 1000 in the two preceding weeks, declined to 12·7 in the week under notice. During the first four weeks of the current quarter the death-rate in these eight towns averaged 13·3 per 1000, and exceeded by 0·3 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 8·1 and 11·1 in Aberdeen and Paisley, to 14·2 in Greenock and 15·4 in Perth. The 460 deaths from all causes in the eight towns last week showed a decline of 10 from the number returned in the previous week, and included 48 which were referred to the principal epidemic diseases, against numbers declining from 83 to 47 in the four preceding weeks; of these 48 deaths, 25 resulted from diarrhœa, 7 from scarlet fever, 6 from diphtheria, and 3 from "fever," but not one either from measles or small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·3 per 1000, and corresponded with the rate from the same diseases in the 77 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had declined in the four preceding weeks from 51 to 25, were again 25 last week; they included 11 in Glasgow, 4 both in Edinburgh and in Dundee, 3 in Aberdeen, and 2 in Greenock. The 7 fatal cases of scarlet fever showed an increase upon recent weekly numbers; 2 occurred both in Glasgow and in Perth. The deaths referred to diphtheria, which had been 15 and 13 in the two previous weeks, declined last week to 7, of which 3 were returned in Glasgow and 2 in Paisley. Four of the 6 fatal cases of whooping-cough (an increase of 2 upon the number in the previous week) occurred in Glasgow. Of the 3 deaths referred to "fever," 2 were certified as enteric fever and 1 as cerebro-spinal meningitis; 2 were returned in Glasgow and 1 in Perth. The deaths referred to diseases of the respiratory system in the eight towns, which had been 69 and 80 in the two preceding weeks, declined again last week to 72, but exceeded by 4 the number in the corresponding week of last year. The causes of 18, or 3·9 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 569 births and 372 deaths were registered during the week ending Oct. 29th. The mean annual rate of mortality in these towns, which had been equal to 15·9, 16·9, and 17·4 per 1000 in the three preceding weeks, declined again to 16·8 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these Irish towns averaged 16·8 per 1000; the mean rate during the same period did not exceed 13·0 in the 77 largest English towns and 13·3 in the eight principal Scotch towns. The annual death-rate during last week was equal to 16·6 in Dublin, 15·3 in Belfast, 17·1 in Cork, 21·6 in Londonderry, 21·9 in Limerick, and 13·6 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 19·5 per 1000. The 372 deaths from all causes in the 22 town districts last week showed a decline of 12 from the number in the previous week, and included 33 which were referred to the principal epidemic diseases, against 31 and 42 in the two preceding weeks; these 33 deaths were equal to an annual rate of 1·5 per 1000, the rate from the same diseases last week being 1·3 both in the 77 English towns and in the eight Scotch towns. The 33 deaths from these epidemic diseases in the Irish towns last week included 20 from diarrhœa, 3 each from measles, whooping-cough, diphtheria, and enteric fever, and 1 from scarlet fever, but not one from small-pox. The 20 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 10 in Belfast, 3 in Dublin, and 2 both in Limerick and in Clonmel. The 3 fatal cases of measles occurred in Portadown, and the 3 of diphtheria in Dublin. One death each from scarlet fever, whooping-cough, and enteric fever were also returned in Dublin; and the other two deaths from enteric fever occurred in Belfast and Cork. The deaths in the 22 towns last week included 66 which were referred to pneumonia and other diseases of the respiratory system, against 66 and 63 in the two preceding weeks. The causes of 14, or 3·8 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·7 per cent., while in the eight Scotch towns it was equal to 3·9per cent.

"Audi alteram partem."

REPORT ON THE MEASURES TAKEN AGAINST MALARIA IN THE LAHORE (MIAN MIR) CANTONMENT.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 29th you deal with this publication, which is the report of a Committee appointed by the Government of India in October, 1909, to investigate a so-called experiment which has been carried out for several years to test the practical applicability of mosquito reduction. The report is now under exhaustive analysis; but, as it may injure the cause of sanitation among those who are not acquainted with such matters, I trust that you will kindly publish the following summary of the criticisms which I have to make regarding it.

1. In paragraph 11 of the report, the object of the experiment is described as being to test the doctrine that malaria can be banished by mosquito reduction anywhere at very little cost. This absurd proposition is fixed upon me by means of quotations taken from my writings and separated from their context. What I taught was that mosquito reduction may be comparatively easy and inexpensive under very favourable circumstances; and this has proved to be the case at Ismailia, Athens, and other places.

2. In paragraph 10 the committee give the misleading impression that Mian Mir was selected for the experiment only after a careful review of other stations in India. As a matter of fact, the gentlemen who chose it had spent only a few months in India, and were directed to Mian Mir from Simla. The place proved to be an exceptionally difficult one, because it is absolutely flat, has an impervious subsoil, and becomes practically a large marsh during the rains.

3. The first operations of 1902–03 were destructively criticised by several writers, including myself.[1] But the Committee accept the soundness of the work without attempting to answer our objections.

4. More extensive measures were adopted under General Kitchener in 1904–05, by cutting off the irrigation system and filling in pits and depressions; but the Committee fail to demonstrate the essential point—namely, whether anything approaching the same thoroughness was shown during the four years from then up to the date of their visit in 1909. On the other hand, they admit that the work was incomplete; that "the military authorities dealt only with breeding places lying within the inhabited portion of the cantonment or situated fairly closely to it"; and that the officers

[1] Brit. Med. Jour., Dec. 17th, 1904, and Journal of the Royal Army Medical Corps, August, 1904, and July, 1905.

employed frequently complained of the inadequacy of the working staff, especially during the rainy (i.e., the malaria) season. They omit to give exact details, month by month and year by year, of the number of men employed and the work actually done, even during the year of their visit. They describe the large use made of military labour, but I gather that this was employed only in 1904–05. They state that an "immense amount has been done to abolish the breeding places of *Anopheles* mosquitoes," but give no figures as to the approximate degree of the sterilisation—was it a quarter, a half, or three-quarters? They did not make their visit until a month after the rains had ceased—that is, at a time when they could not possibly have observed fully for themselves the incompleteness of the measures (though even then breeding places remained). Their evidence was therefore mostly obtained from witnesses whose statements are not given *verbatim*. On the other hand, a writer who has recently visited the place says[2] that "no attempt whatever is made to prevent the establishment of breeding places within the courts of the houses," and that, "excellent as they are, the measures hitherto adopted are by no means complete, and cannot be taken as any indication of the final potentialities of anti-malarial sanitation in the locality."

5. Exact accounts of the expenditure, month by month and year by year, would have revealed the sufficiency of the operations—or, perhaps, their great insufficiency during recent years. The Committee state, however, that they cannot "give even an approximate estimate of the total cost of the operations." Yet this was supposed to be a practical experiment! Surely they might have furnished the details for the year or two preceding their visit. We learn that Rs.33,849 (about £2256) were spent in connexion with the operations of 1904–05, mostly on obliterating the irrigation system. This was a measure of doubtful utility, since an excellent irrigation system is now maintained without mosquito breeding at Ismailia, so that it is open to question whether most of this expenditure with its contingent loss of revenue (not clearly given) should be included in the bill. The reform of the surface drainage in 1905 cost Rs.40,000 (£2666), but much of this was required for ordinary sanitary purposes. All we are clearly told is that "from 1906–1907 onwards a total sum of Rs.14,594 has been spent from cantonment funds on various anti-malarial operations"—no exact details. We learn, however, from Colonel Rowan, R.A.M.C., who actually supervised the work, that "the diversion of the canal entailed a loss of revenue to the cantonment fund of about Rs.6000 yearly, and the actual filling in of the canal cuttings and the digging of wells to replace them, together with some minor sanitary improvements, cost about Rs 15,000. Since 1905 the cantonment fund has granted annually Rs.1000 for anti-malarial work."[3] Hence it appears that since 1905 the princely sum of £66 a year was allowed for the work. This, be it remembered, for a difficult country of eight square miles occupied by five regiments and a total population of 16,000 people! The sum amounts to 1 anna (about 1*d.*) per head of population and 1·7 per cent. of the annual income of the cantonment (Rs.60,000), and explains the inadequacy of the working staff complained of by the local officers (who, I should add, were not in any way to blame for it). Would any practical sanitarian admit that any disease like malaria could be eradicated from such a place for such a sum? The whole thing is not a fair test of my proposals and amounts to nothing more than a travesty of them.

6. Nevertheless, wonderful to relate, as shown by Chart I. of the report, the statistics demonstrate an extremely low malaria-rate among the troops, especially during 1904–07, when the operations were most thoroughly conducted. The Committee attempt to parry this fact by arguing that a similar decline has occurred in other stations, especially Amritsar, where they say anti-malarial operations have not been adopted "on a large scale." But they did not visit these places and give no facts to prove that no anti-malarial operations were adopted in them. I am therefore free to maintain, pending further and more reliable analysis, that the general improvement, including that at Mian Mir, was due to precisely similar partial measures carried out by the military—namely, improved drainage, partial mosquito reduction, and partial quinine prophylaxis. If they prove anything (which is doubtful), the Committee's facts prove just the opposite to their conclusions—they suggest that the trifling expenditure of 1 anna per head has been at least accompanied at Mian Mir by an exceptionally low malaria-rate.

The Committee's figures will be much criticised. They omit to describe changes among the bodies of troops and the effect of the outlying post of Fort Lahore, said to be an intensely malarious spot. Both of these factors should largely increase the malaria-rate at Mian Mir. The figures for the native population cannot be accepted without consideration of many factors not mentioned in the report. Deaths and invalidings among the troops are not given.

7. It will be agreed that for a cost of 1 anna a head no sweeping reduction of mosquitoes and malaria, such as occurred at Ismailia, could be expected, especially just after a heavy rainy season. The Committee's own efforts (lasting six days) to measure the variation by means of the most grotesquely insufficient random sampling are not capable of detailed examination in this brief review. For example, in the British Infantry Bazaar, enlarged spleen was found in 20 out of 25 children examined in 1901, and in 17 out of 24 children examined in 1909. They gravely put down (p. 31) the corresponding percentages as being 80 per cent. and 71 per cent. respectively, and then argue that this shows no great reduction. But the statistical errors are respectively 22 per cent. and 26 per cent., so that the variation may have been anything from an increase of 39 per cent. to a decrease of 65 per cent., and in the latter case the reduction would have been very great. Similarly with the other samplings, and, owing to close localisation of malaria and to the neglect of the courts of the houses just mentioned, each sample must be taken by itself. The Committee are so oblivious of these matters that they sometimes omit even to give the actuals at all. In 1904 I exposed the utter untrustworthiness of these methods and those employed for estimating the number of mosquitoes; but the committee repeat the blunders without answering my criticisms—a thing which amounts merely to an appeal *ad ignorantiam*.

8. Perhaps the most "colossal blunder" in the report is the omission of all reference to the *cost of the disease*. The fundamental economical principle of malaria reduction is that it will reduce that cost. For deaths, invaliding, medical upkeep, loss of service and of military efficiency among the 4000 soldiers at Mian Mir, malaria must cost Government directly a very large annual expenditure. Each British soldier is said to be worth £100 to Government, and each invaliding and sick furlough to England costs, I suppose, quite £50; so that Rs.100,000 a year (about £6666) would probably be a low estimate for the cost of a disease which has caused an admission-rate of 100 to 300 per cent. of strength in the station. And what must be the cost to the large civil population? I doubt whether the whole expense of the Mian Mir work from its beginning has equalled half the cost of the disease during a single year. If the disease costs Government Rs.25 a year for each soldier there, the one anna a head which has apparently been recently devoted to prevention is only 1-400th part of that cost. But all this is absolutely ignored, not only in this report, but in all the previous official reports on this subject, the pretence being that the few pence a head required for mosquito reduction are much more than can be afforded.

9. The committee's scanty account of campaigns outside India is mostly derived from occasional papers, and largely from mine. It makes no attempt to analyse either the results or the cost. Professor Osler has already adjusted their statements regarding Panama.[4] Colonel Gorgas says in his contribution to my recent book on the prevention of malaria that mosquito reduction costs $2 a head of population in Panama; but the cost of labour there is probably four or five times what it is in India, and the campaign was waged against yellow fever as well as malaria, and is much more sweeping than I ever suggested for India. The other campaigns are treated in the same manner. No attempt is made to extricate the facts for the purpose of a worthy review of the subject, and one would think that the Indian sanitary officials have never tried to ascertain these facts for themselves by special inquiry.

10. The greatest credit must be given to the military medical officers at Mian Mir for the manner in which they conducted the work with the small pittance allowed them for it. They frequently pointed out in recent years the necessity for more funds (their complaints are mentioned in the report), but none were granted. Thus, though malaria cost

[2] Journal of Tropical Medicine, May 16th, 1910.
[3] Journal of the Royal Army Medical Corps, September, 1908.

[4] THE LANCET, Oct. 8th, 1910.

Government, say, Rs.100,000 a year, the utmost that "economical administration" could allow for its prevention was, say, Rs.1000 a year. I see, however, from p. 5 of the report that the authorities did not hesitate to spend Rs.218,000 for an additional water-supply, which, however, turns out to be brackish! One can, therefore, spend 2 lacs for brackish water and 1 lac a year on account of malaria, but £66 a year is, in the sense of the committee, an inordinate expenditure for attempting to control that disease. The question arises whether the whole Indian sanitary system does not require, not reformation but revolution. When we note further that the pay of a single senior Indian official is often Rs.2000 a month, and that this will pay for 200 coolies at Rs.10 a month each, and that the permanent petrolage gang at Mian Mir seems to have fallen in 1909 to *four men and a hospital* assistant (p. 19), we shall, I think, conclude that this question is perhaps the most urgent one at present for India.

So much for Mian Mir. I think that all those who are interested in the saving of human life on a large scale would like to ask the following questions regarding the matter. Here we have a so-called experiment carried out to test a new sanitary measure proposed for the prevention of a disease which in India alone causes every year at least 1,000,000 deaths and say 100,000,000 cases of illness. Why, then, was not the experiment supported by the Imperial Government with sufficient funds (in addition to the miserable dole allotted from the cantonment fund) to ensure at least some genuine attempt at marked success? Why were not the measures of 1904–05 continued and maintained? Why were no exact records kept (or at least published) of the number of men employed, the work done, and the money spent month by month and year by year since then? Why, instead of the admittedly faulty military statistics, were not accurate measurements made by proper methods of the fluctuating amount of malaria in the place? Why is there no mention of the cost of the disease? And why were no efforts made to obtain accurate accounts of other campaigns? As, moreover, the whole affair was admittedly undertaken to test proposals attributed to me, would it not have been more courteous to have consulted me sometimes on the matter, instead of publishing under the sanction of the Government of India report after report full of omissions, hasty observations, and ill-considered conclusions which can only mislead the ignorant on a matter of life and death to millions? If I were to maintain that the whole affair was meant, not to test my proposals, but to discredit them, it would be difficult to refute me. It is easy to allow any experiment to fail if we wish it to do so.

But it is no longer possible to take the matter seriously. The reports are too clearly lacking in precision either of fact or of thought to be capable of adding anything to our knowledge of the subject. The whole point of the alleged experiment was really to compare the cost of the disease with the cost of its prevention; but the Committee have entirely ignored the former point and have admitted their inability to give "even an approximate estimate" of the latter one, and the result is therefore an absolute zero. Mian Mir proves nothing. If it *suggests* anything, it suggests that a trifling expenditure of 1 anna a head per annum was, as I have said, associated even there with a considerable fall in the malaria-rate. The Government of India have evidently been misled into the belief that mosquito reduction will ruin them and are therefore trying hard to escape from the responsibility; but the practical feasibility of the measure is now too well established by sound work elsewhere to be dismissed by such extraordinary hebetudes as are contained in these publications. I hope to discuss elsewhere the general question of malaria prevention in India.

I am, Sir, yours faithfully,

University of Liverpool, Nov. 1st, 1910. RONALD ROSS.

EFFICIENT VENTILATION.

To the Editor of THE LANCET.

SIR,—I have read with some astonishment Dr. Leonard Hill's letter in your columns on this subject and venture to offer some remarks, feeling that in its present form, and having regard to the eminent position of the writer in the physiological world, this letter is likely to do much harm. From it one would conclude that the effects of breathing impure air can be nullified by setting the air in motion. Judging from the reasons given, it would be as logical to say that if a cart-horse is overloaded the remedy is to flog him.

Some years ago I entertained 20 (mostly medical) men in a room 20 feet by 15 feet by 10 feet. It was a hot summer's evening, the external temperature being 80° F., the interior a little higher. I passed a plentiful supply of air through the room, but there was no appreciable movement of air; in spite of the high temperature my guests expressed themselves as feeling quite comfortable. I then struck off the air-supply and in a few minutes the air became oppressive. On taking the pulses and respirations I found that the former was in every instance considerably increased, in some nearly doubled in frequency. The number of respirations was also very much increased. On renewing the air-supply all the occupiers of the room experienced a refreshing feeling and their pulses and respirations returned to normal. Now in this case there was no question of any appreciable movement of air such as might act as a stimulant to the skin. I think this observation is a physiological proof of the ill-effects of impure air *per se*. I am willing to admit that the discomfort experienced by breathing foul air, especially when overheated, is partially removed by setting the air in rapid motion, but as I have said before this is only a palliative measure.

I do not think Dr. Hill can be serious in maintaining that fans placed in a room where persons are breathing foul air can be looked upon as a remedy, and this is why I feel it is important that his letter should be called in question. This method is the one caught at by many who wish to avoid their obligation to provide good ventilation. Within a mile of THE LANCET Office there are hundreds of rooms in which employees are packed without any proper provision of fresh air, and if the idea became general that the supply of a few revolving fans to throw the air about constituted efficient ventilation, this condition of things is likely to be perpetuated. I think Dr. Hill does well to contradict the very widely spread notion that CO_2 in quantities usually found in crowded rooms is deleterious. This notion has long since been proved a fallacy, but impressions such as these when widely spread and copied from book to book die hard.

Dr. Hill says: "There is no evidence worth a jot that the traces of organic material found in close air are harmful." I quite agree with him, but think this is due to the fact that our present methods are not sufficiently delicate, nor our knowledge of chemistry sufficiently advanced for us to appreciate the substances which are thrown off by the respiration of the lungs and skin. I think here a remark by Dr. M. H. Gordon comes to our rescue, where he advocates the use of our subjective feelings as a test. I personally have used no other method lately, but have simply gone on the principle of "the proof of the pudding is in the eating." Before they dogmatise on this point I should like to ask chemists and bacteriologists what is their explanation of the fact that air in a crowded apartment during waking hours has a different smell from that in a crowded dormitory? As a convenient expression I have given the name of spiral toxes to these mysterious substances. I am inclined to think that they are only slightly diffusible in air, suggesting a particulate constitution like that of smoke or fog. On approaching the door of a crowded church we appear to come suddenly on to a bank of fœtid air. The lack of diffusibility would account for the fact that the atmosphere in different parts of a room varies very much as to its stuffiness, although the motion of the diffusible gases CO_2, vapour of water and so forth, may be found uniform throughout the room. With respect to humidity I have come to the conclusion that the air-supply to an occupied room cannot be over-dried; the trouble is to keep the air in a room from becoming over-moist. In the cases where discomfort arises from the heating of the air this is due, I believe, always to errors in method of heating. The heating of air at present is usually effected by means of apparatus constructed of iron.

A year or two ago I made some experiments on this subject and found that if I heated iron above 80° F. it began to smell and produce what is usually called the flat-iron smell. When we remember that hot-water apparatus are usually employed at 180° it is obvious that the air as it enters the room must become vitiated. It is usually supposed that this smell depends upon the over-heating of organic matter in the air; this is quite fallacious. There is a very definite smell attached to every metal when heated, so much so that by practice it would be possible to identify a metal by means of its specific smell. With this fact in view I arranged the heating

apparatus for the new examination hall at Cambridge of such a capacity that it is not necessary for the heating services to be raised above 80°. This, of course, was a costly matter, but the result has fully justified the large expenditure. I have on the same principle arranged electric air heaters that contain a minimum of metal. By this arrangement vitiation of air is avoided. Control is obtained over the temperature by means of switches which call into use various sections of the apparatus. It will, I think, be a surprise to many to hear that when rooms are only occasionally used it is found cheaper to heat the air by this method than by hot water or steam.

In conclusion, I wish to emphasise the fact that for all practical purposes, if we want good ventilation, we must supply the proper amount of air. It must be properly distributed and removed, and must not be wasted by short circuiting. Efficient ventilation cannot be achieved by physiological juggling.

I am, Sir, yours faithfully,

Oct. 26th, 1910. THOS. GLOVER LYON, M.A., M.D.Camb.

THE RESEARCH DEFENCE SOCIETY AND PROPHYLAXIS AGAINST PLAGUE.

To the Editor of THE LANCET.

SIR,—In connexion with the cases of plague in Suffolk, let me say that this society has lately published an illustrated pamphlet on "Plague in India, Past and Present," by Lieutenant-Colonel Bannerman, M.D., D.Sc., director of the Bombay Bacteriological Laboratory. It gives a full account of the experiments which proved that fleas carry the plague from rats to man; it also gives a full account of Haffkine's preventive treatment, and of the many thousands of lives that have been saved by this treatment. I am sorry that the Research Defence Society cannot afford to give away this pamphlet in large quantities; but I shall be happy to send it to any of your readers who will send me seven stamps. I shall also be happy to send copies, on sale or return, to all booksellers.—I am, Sir, yours faithfully,

STEPHEN PAGET,
Honorary Secretary, Research Defence Society.

21, Ladbroke-square, London, W., Oct. 31st 1910.

A CASE OF HOMICIDAL DROWNING OF A BOY, AGED SEVEN, IN WATER 3½ INCHES DEEP.

To the Editor of THE LANCET.

SIR,—On August 19th, at about 5 o'clock in the afternoon, I was summoned to a village some three miles distant from Bicester to see a cottager's son who had been drowned, it was alleged, by his insane mother. I found the body of the boy, aged 7 years, lying in the cottage "wash-house" at the side of a zinc washing-tray (22 inches long by 18 inches wide), which contained only 3½ inches of water. Life was extinct, though the corpse was still warm. The boy was fully dressed but for his jacket and boots, and his shirt-sleeves were tucked up as if in preparation for a wash. There were no marks of violence. The skin was blanched, the lips blue, the pupils widely dilated, and some white froth had issued from both nostrils. A post-mortem examination made subsequently revealed the ordinary signs of suffocation from drowning.

The history of the case was that about 3 P.M. the woman was left alone in the house with her little boy by her grown-up daughter, who at that time took tea to her brothers in the harvest field. Shortly afterwards the next-door neighbour, an old cripple just able to hobble about with the aid of two sticks, heard three screams which he recognised as coming from the child in his neighbour's "wash-house." He took no immediate action as he suspected nothing. A few minutes later, however, he was startled by the frenzied mother, who rushed into his garden calling out that she had drowned her child. He immediately sent for the woman's husband and went across to the "wash-house," where he found the body of the boy leaning over the side of the washing tray with his face and hands in the water, and resting on the bottom. He laid him out on the floor and, having "rubbed him well and pressed his bowels once or twice" to no effect, he came to the conclusion that the boy was dead.

The case has since been before the Oxford assizes, when the mother, who was found guilty of causing the death of her child though not responsible for her actions, was ordered to be "detained during His Majesty's pleasure." The woman had, a few months before this unfortunate happening, been under treatment for melancholia. I had warned her husband of the danger of leaving her unwatched and had also advised her removal from home. It was sad that neither the old man, who was so near at hand, nor any of the others who arrived on the scene immediately afterwards knew anything about artificial respiration.

I am, Sir, yours faithfully,

ROBERT L. GLASS, M.R.C.S. Eng., L.R.C.P. Lond.

Bicester, Oxon., Oct. 25th, 1910.

THE TERRITORIAL FORCE AMBULANCE SERVICE.

To the Editor of THE LANCET.

SIR,—When I wrote in your columns of Oct. 15th that the *Hospital*, in stating that almost the sole *raison d'être* of the Order of St. John of Jerusalem was its ambulance department, overlooked the great history and traditions of the Order, I deemed myself, and still deem myself, justified in my criticism. But as the *Hospital* has now stated that it "is not unmindful or careless of the past glories of the Order, I admit misapprehension of its meaning, but not "misquotation." This, however, is a mere trifle. The important point at which every right and fair-thinking man wishes to arrive is the provision of a competent ambulance service for the Territorial Army.

What the British Red Cross Society has been able to achieve up to the present time is fully set forth in a statement issued by the society which appears in the *Morning Post* of Oct. 24th. The one thing that the inditer of that roll of achievement forgot to add was the obligation of the British Red Cross Society to the ambulance department of the Order of St. John of Jerusalem. The "*personnel* of 6222" forming the 202 voluntary aid detachments are all, or almost all, men and women trained by the St. John Ambulance Association. I received recently a copy of the last report of the county director of Devonshire, in which, after naming six institutions competent to grant certificates qualifying for admission to voluntary aid detachments, he adds, with some *naïveté*, "But, as the St. John Ambulance Association alone of these six has a branch working in this county, I recommend all to make use of it *for the present*," or words to that effect. What is the case in Devonshire is the case in all, or most, of the 44 counties in which the Red Cross Society has branches.

In an article which I recently contributed to the *National Defence Magazine* I pointed out that the British Red Cross Society had undertaken to provide two things—viz., a manual of instruction for the detachments and an inspecting staff. I note that the report in the *Morning Post* entirely ignores these two most important points; and the natural inference is that neither manual nor inspecting staff as yet exists. How are the voluntary aid detachments to be trained and maintained efficient without them? I am amused at the 170,000 documents issued from the central office "as a proof of work done," and the careful mention of the high nobility who lead the Red Cross movement. I wrote correctly three months ago for the *National Defence Magazine* that the chief part of the work of the headquarters of the Red Cross Society consisted in "a prodigious amount of memoranda and forms and the invocation of all the deities of social influence."

I am, Sir, yours faithfully,

The Athenæum, Oct. 26th, 1910. A. C. YATE.

PS.—I am perfectly aware that in this letter I only touch one or two tags of the fringe of this question. The crucial point is involved in the now much debated problem of compulsory *v.* voluntary service—the problem so ably treated by Lord Curzon at Hanley. If service in our army of defence becomes a national duty, service in its ambulance service will be equally so; and so, in my opinion, it should be.—A. C. Y.

SANITARY PROGRESS AT COPENHAGEN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(*Concluded from p. 1309.*)

The Milk-supply.

IN my previous article I said that I would deal later with the question of the milk-supply of Copenhagen. That side of the sanitary progress of the Danish capital is worth full consideration, for the authorities have arrived at something like a satisfactory solution of some difficult problems. Some thirty years ago the milk-supply of Copenhagen was bad, and its method of distribution reprehensible. The distillers sold their distillery waste or mush to the dairymen who fed their cows with it, and in exchange the distillers bought and retailed the milk, and the public had to go to a vodki shop for it. Many cows were kept in the town where they were not only fed on such unsuitable food as the distillers' mush, but were stabled in overcrowded, ill-ventilated, and dirty sheds. There were no veterinary surgeons to inspect these premises, and hardly any measures were taken to ensure either the quality or the purity of the milk. In time the authorities woke up to the risks endured by the public, and it seems that the first steps taken were directed towards preventing the addition of flour and water to the milk. If reference is made to the earliest analyses, of which a record has been kept, it will be seen on what an extensive scale milk was adulterated in this way. When the control of the milk-supply by the police began to be effective the milkmen employed two sorts of cans; the one contained pure milk, the other they declared contained skimmed milk. As such the police inspector would recognise that both articles were sound, but directly the inspection was over there was nothing to prevent the milk-dealer from mixing the skimmed milk with the pure milk and selling the mixture as genuine milk fresh from the cow. Preservatives were also used and this to an undue extent, whereby children and invalids suffered.

Increased Expenditure and Smaller Profits.

The starting point of reform was due to an interesting incident. A merchant of Copenhagen, Mr. G. Busck, noticed that one of his workmen seemed worried and inquired the cause. The workman replied that he was anxious about the health of his child. The distiller who supplied him with milk for his child had refused to do so any longer because he did not buy spirits as well as milk. Mr. Busck was so impressed by this state of affairs that he appealed to men distinguished for their public-spirited and disinterested conduct, such as Professor Panum of the University, the Court Chamberlain, M. Bille, former Ambassador at Washington, Professor Borch, and Professor Englested, and asked their help in starting a society for the purpose of giving the population an opportunity of obtaining "pure milk from healthy cows." This society was founded in the spring of 1878 with the small capital of £500 and the understanding that no one should receive more than 4 per cent. interest for his money.

From the very first the Copenhagen Milk Supply Co., as this society styled itself, grew rapidly, and its efforts were greeted with great sympathy, everyone realising the need of pure milk. But this meant a complete reform of all the processes from the cow to the house of the consumer. Every detail in the existing milk-supply had to be modified, and pressure was at once brought to bear on all the persons concerned to make them consent to the extra trouble and extra expense entailed by all these alterations. First of all, the cows had to be fed on proper food and not distillery slops, which produces the largest quantity of inferior milk. Then the cows had to be housed in a sanitary manner. When it came to milking the cows a number of precautions had to be introduced, of which the farmer had no conception. But a distinction must be made. There are two sorts of milk needed: the one that is destined to replace mother's milk for artificially fed infants and the other ordinary milk for the everyday use of adults. From the first it was recognised that the ordinary milk and the "Bornemaelk," or "milk for infants," might need different treatment.

Milking the Cows in Copenhagen.

For milking a cow the ideal is the open field, where the fresh winds blow, the sun shines, and the air is pure. In winter, however, the cows are milked in their stables, but this must never be done at the time of cleaning, when there is too much dust about. Further, if the milk is for the feeding of infants the cow is taken out of the stable and passes through a compartment where it receives a final brushing before it is admitted to the special milking room, which is kept beautifully clean, well lighted, and ventilated. Here the milk-maid, wearing a spotless white dress, first wipes the cow's udder with a damp cloth. Then she washes her own hands before milking. The first two or three jets from each teat go to a separate pail and are used for farm purposes. For ordinary milk the milking may take place in the stables, but in either case the cows are shaved near the udders so as to lessen the risk of dirt falling into the milk, and the milkmaids wash their hands and the teats before milking. The cows that supply the milk for infants are examined twice every month by a veterinary surgeon, and a report is then drawn up as to the state of the stables, the nature of the food given to the cows, and whether there is sufficient ice on the premises. The milk also is only taken from cows that have been submitted to the tuberculin test. The first step, therefore, is to obtain milk that is thoroughly good and to prevent its contamination during the milking process. No amount of boiling or pasteurising will make good milk of bad milk.

Preservation of the Milk.

But having obtained good sound milk from a healthy cow, there come the problems of its preservation and conveyance from the farm to the consumer. The system of preservation employed is based on extreme cleanliness, and on the use of ice to lower the temperature. For the infants' milk-supply not only, as already described, are extra precautions taken in milking, but a special pail is used. Fixed to the bottom of this pail is placed a pear-shaped copper receptacle (Fig. 1).

FIG. 1.

Milk pail with pear-shaped receptacle to contain cooling mixture.

On turning the pail upside down this receptacle can be opened and filled with a mixture of one part of common salt with three parts of ice or snow. The lid is then screwed on, and we have within the pail a large cooling surface. By using one of these pails the temperature of the milk is at once reduced to 70° F., whereas in an ordinary pail the temperature of the newly-drawn milk exceeds 80°. The cooler the temperature, the less is the development of organic life favoured. Experiments have been made. From two teats of a cow six quarts of milk were milked in one of these refrigerator pails. From the other two teats of the same cow six more quarts were milked into an ordinary pail. Then the milk was placed side by side in bottles in a room where the temperature was 60°. The milk from the ordinary pail was the first to turn sour and the other remained pure a much longer time. This trial was repeated, but this time the teats were carefully washed. Though these precautions were taken in regard to both pails, the milk from the ordinary pail went bad after 82 hours and that from the refrigerating pail after 144 hours. Then the same experiment was made without washing the udders but drawing the first jets of milk into a separate pail. The milk from the ordinary pail kept fresh for 52 hours and that from the cooled pail 96 hours. On repeating this same experiment, but omitting to draw off the first few jets of milk into a separate pail and keeping them away from the bulk of the milk, that which was gathered in the ordinary pail showed signs of deterioration after 40 hours and that from the refrigerated pail remained sound for 70 hours.

Discipline by Money.

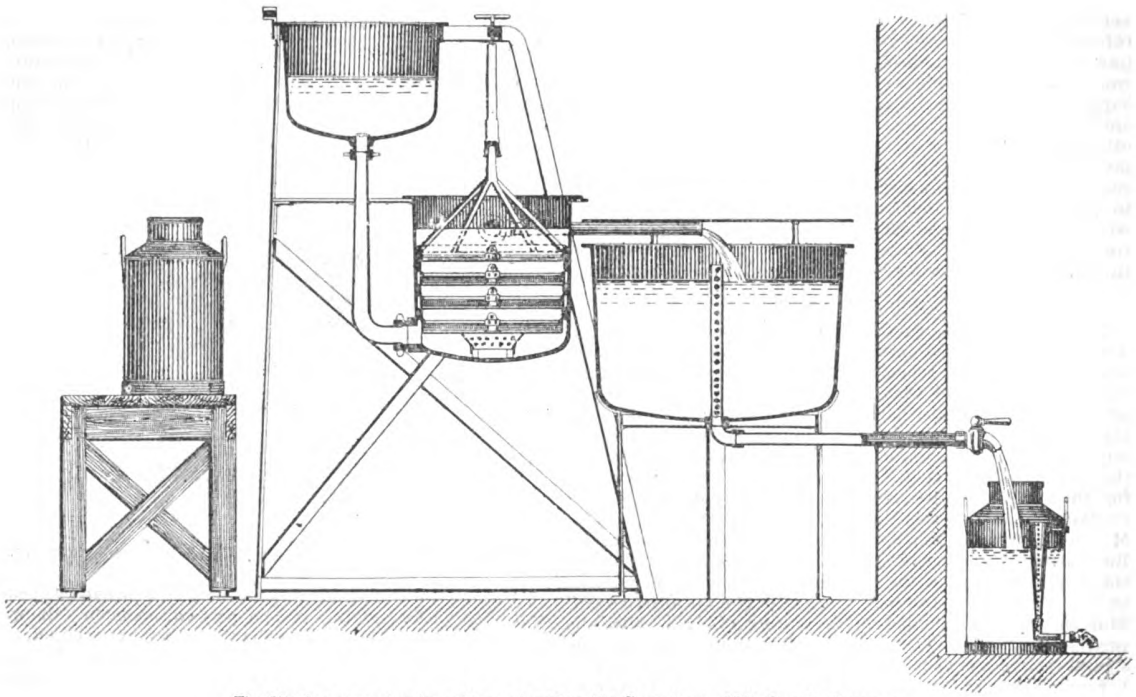
All this is of scientific interest, but how are rough-and-ready farm hands to be taught the importance of these aseptic principles? Where also is the authority to enforce such measures? In the absence of laws and of police the only force that could be brought to bear was the power of money. Rules and a complete scheme of dairy-farming were presented to the more intelligent farmers. If they chose to incur the trouble and expense of keeping cows and collecting the milk in the manner and with the precautions indicated, then the Copenhagen Milk Supply Co. would buy this milk at a much higher price than its ordinary market value. But this did not suffice. Many farmers accepted these terms, and were doubtless quite desirous of carrying out all the stipulations, but why should the farm hands and dairymaids give themselves all this extra trouble? They were not interested in the sale of milk. Thereupon the Milk Supply Co. determined not only to pay the farmers more for their milk, but it decided to give a present or bonus of 10 to 20 kroner (11*s.* to 22*s.*) per month to the men who have charge of the cows and whose business it is to keep them and their stables thoroughly clean. The milkmaids also receive a bonus of half the amount, and inspectors constantly go round to see if these bonuses have been earned, and that the farmer on his side is carrying out his bargain. Instant dismissal of the workpeople or cessation of business with the farmer is the penalty of any infraction of the rules. In the absence of laws on such matters there can be no other method. To pay better than the market price is the one and only force private enterprise can employ.

There is yet another and very grave matter in regard to the farm or source of supply. Illness may occur and the patient may contaminate the milk. To meet this contingency the company desires that when illness is suspected no milk should be forwarded till after medical advice has been obtained. Any loss that this may entail on the farmer will be refunded by the company. Thus all fear of losing money through taking proper precautions is removed. If the medical adviser thinks the illness is not serious and there is no danger of milk contamination, then the business relations are resumed as before. If, on the contrary, there is danger, then the State takes the matter in hand. The company, however, has just stepped in to fill that important gap in the chain between the mere suspicion of illness and the actual intervention of the public health authorities.

The Milk at the Town Depôt.

Such are the measures taken to secure a supply of good and pure milk, but there yet remains the very great difficulty of conveying this milk from the farm to the town depôt, and thence to each individual consumer. How this is done I was able to see by passing a portion of the night at the great depôt, situated in the outskirts of Copenhagen. Here a branch line enables the milk trains to reach the doors of the depôt. The milk-cans are provided by the company: square cans of 50 litre capacity for ordinary milk and round cans of 40 litre capacity for milk for infants. These are sealed down at the farm and bear the name of the sender. In summer the railway vans are provided with ice to keep the milk cool. On the railway platform hand trucks receive the milk cans, and these are wheeled into the depôt. A clerk notes whence each can comes. It is then weighed. The can is now opened. A woman introduces a lactometer; at the same time a sample is taken, partly for the laboratory and partly for the milk-tasters. These latter are women, and they have to taste 150 samples a day. They can easily detect if there is an unusual flavour, in which case the can is set aside for analysis and more elaborate examination. The temperature of the milk is also taken, and should it prove not cool enough the persons who have supplied the milk are warned. If, as is usually the case, the milk is found to be good, it is then poured out of the can over a sieve into a vat or tank. From this receptacle the milk is pumped up over what is known as a Lawrence cooler. This consists of a pipe twisted round to form a cone and the milk pumped over the top and narrow end of the cone falls over it in a thin sheet. As the cone contains iced water this cools the milk. The water in the cooler travels backwards and forwards from a large ice-box. The milk thus cooled is now filtered. The filtering apparatus consists of two receptacles, one several feet higher than the other (Fig. 2). The second and lower receptacle is filled with fine gravel. There are wire gauze partitions to prevent clogging, and at the top there are three or four layers of very fine cotton tissues, such as muslin or cheese cloths, that act as further filtering or clarifying material. The object, of course, is not to filter in the laboratory sense of the word, but to extract any grit, hair, dust, or other foreign matter that may be in the milk; and it is wonderful what a large quantity of foreign substances does get mixed with milk. A pipe unites the two

FIG. 2.



The filtering apparatus for milk employed by the Copenhagen Milk Supply Company.

receptacles, and the milk, by the force of its own weight, travels up through the filter and out by the top of the lower receptacle. It is then received in cans or bottles, as the case may be, and is ready for delivery. The boxes to hold the bottles are provided with ice; the milk is never allowed to get warm.

How to Draw Milk from a Can.

The milk is delivered direct to the consumer; it is not entrusted to the tender mercies of a retail dealer, by whom, if it is not adulterated and wilfully tampered with, it is, nevertheless, through ignorance or carelessness, likely to be contaminated or befouled. It has been thought preferable to build large stables, purchase 80 horses, and create a perfect arsenal of carts, so that the milk might be delivered in an absolutely pure condition to the consumer himself. These carts are closed on all sides and in themselves represent quite a revolution in the old methods of the trade. Inside are large milk-cans with taps coming through small apertures in the side of the cart. Here there are one or two small apertures which are only opened when milk is required. The measures for the milk have handles so constructed that they must be put by in such a manner that dust cannot fall inside. But the most thoughtful contrivance is that which is put within the milk-can itself. As with milk the cream gathers on the top, it follows that the milk in the higher part of a big can would be of better quality than that at the bottom. Therefore the milk should be drawn from all parts of the can and not merely from the bottom, where the tap is placed. To this end a perforated tube going from the top of the can to the tap might draw off the milk from all parts of the can. But even this would not suffice, for the weight of the milk creates a greater pressure at the bottom of the can. Therefore a pipe has been devised which is smaller at the bottom and has smaller holes. But the pipe widens and the holes are larger and larger as it gets nearer the top of the can. Thus the milk at the top can run in more easily. This compensates the pressure at the bottom, and consequently the customer gets his fair share of top milk. This is shown in the illustration.

Cleanliness and Ice as the only Preservatives.

In regard to the extreme cleanliness observed, I need not describe in great detail the mechanical means employed to clean, scour, and sterilise all the utensils. An important point is to note that where milk is concerned plain cold water must first be used so as to prevent curdling and to get the traces of milk removed. It is not till this has been done that hot water and soda can best be brought into action. In the big cans machine brushes scrub with 600 revolutions in a minute. For cleaning bottles the brush that goes inside makes 1500 revolutions in a minute. The inside of the metallic cans is very smooth, to prevent anything adhering and to facilitate the process of cleaning. After this is over the cans are passed through a 1 per cent. solution of lime-water, then are flushed out with plain water, and finally superheated steam is discharged in each can. This has a sterilising effect, while the heat causes the cans to dry quickly, and there is less chance of rust. The cans are then ready to be used again.

As for the premises where all this is done, they are spacious and airy. They consist of only one lofty floor. The ground is asphalted over. All the men and women employed have to wear white overalls and wooden clogs, as the floor is wet with the washing that is going on all the time. The walls are whitewashed throughout, and no dust or dirt is allowed to accumulate. The ice-house attached to these premises holds 3000 tons of ice, and this figure gives some idea of the important part ice plays in the transport and preservation of milk. The bottles that contain the special milk for infants are placed in ice up to the very last moment. If the milk is kept cool and perfectly clean it will last long enough to be brought to the consumer, who may then drink it in its natural condition, unaltered by the addition of chemicals or by any process of pasteurising, of boiling, or of warming.

The Financial Problem.

The most crucial question is undoubtedly that of the price of the milk. If the milk is to be rendered very expensive by taking all these precautions then the reform will defeat its own ends. But the Copenhagen Milk Supply Co. has effected a great economy by limiting the interest on the capital invested to 4 per cent. and by eliminating the small retailer altogether. It has three milk depôts of its own for the retail sale of milk situated in convenient districts of the town and a small army of carts taking the milk up and down the streets. On these carts is written in big letters what is the price of the milk—namely, 16 öre, or 2¼*d.* a quart, for unaltered pure milk. The special milk for infant feeding is expensive, as it is rather more than 3*d.* the quart, but it is the cheapest form of medicine. Still, the extreme poor cannot be expected to pay this price, and such public or private charities as exist should help to place this more expensive milk at the disposal of poor mothers who cannot suckle their own infants. Altogether the Copenhagen Milk Supply Co. now sell something like 9,000,000 litres of milk in the course of the year. This represents only a portion of the milk-supply of the town, but it constitutes a sufficiently severe competition with the other milk dealers to have had a most wholesome action on the entire trade. It has prevented the raising of the price of milk. Though the price of commodities has often increased, that of milk has remained stationary for the last 32 years. On the other hand, the standard of cleanliness observed and the precautions taken have been radically changed and improved. The other great milk concerns are not actuated by the same philanthropic reasons which constitute the inspiring motive of the Copenhagen Milk Supply Co., but they have all had to imitate, at least to some extent, what was done. Thus there has been an all-round improvement affecting the price and the purity of the entire milk-supply of Copenhagen.

THE RECENT ARMY MANŒUVRES IN THE SOUTH OF ENGLAND.

(BY A SPECIAL CORRESPONDENT.)

(*Concluded from p. 1310.*)

II.

Medical Services.

THE organisation of the medical services was briefly as follows. Cavalry brigade and infantry brigade reception hospitals were organised for the temporary treatment and disposal of the sick. Divisional troops sent their sick to the nearest reception hospital. All medical officers were mounted—horses, saddlery, picketing gear, horse blankets, &c., being provided for captains and lieutenants in medical charge of mounted troops by the officers commanding the units to which they were attached. Medical officers in charge of dismounted units were provided under arrangements made by their brigade commanders. Field medical officers had to arrange to provide themselves with suitable chargers.

Medical officers in charge of troops were provided under brigade arrangements with a regimental non-commissioned officer acquainted with medical inspection duties, and tents, camp equipment, and transport were similarly provided for these officers. The administrative medical officers and sanitary officers were provided with bâtmen under arrangements made by the general officers commanding divisions; bâtmen for the medical officers attached to troops were provided by the brigades concerned. The Royal Army Medical Corps *personnel* and transport with headquarters and brigades were accommodated, rationed, foraged, &c., by the units to which they were attached, the reception hospitals being treated as independent units and not attached to any other unit for these purposes. Stretcher-bearers (with armlets) and stretchers were provided by officers commanding units in accordance with the following scale, and were placed at the disposal of the medical officers in charge of the troops, who were directed to take opportunities, as far as possible, to instruct the stretcher-bearers in their duties.

	Stretcher-bearers.	Stretchers.
Regiment of Cavalry	6	2
Battery of Artillery...	2	1
Battalion of Infantry	8	4

Medical Inspection of Sick.

The sick were seen each morning in time to admit of the cases being disposed of before the troops moved out of camp, and also each evening on arrival in camp. The sick of units which had no medical officers attended at the nearest medical inspection tent.

Disposal of Sick.

All sick men who could not be treated with their units (trivial cases) were sent to the reception hospital. Cases not likely to require more than 24 hours' treatment were detained in the reception hospital. Cases requiring more than 24 hours' treatment were disposed of as follows:—(*a*) If likely to be fit for duty before the termination of manœuvres they were sent to the nearest convenient military hospital at which accommodation was available, due regard being paid to the probable movements of the troops. (*b*) If not likely to be fit for duty before the termination of the manœuvres, the sick were sent direct to the military hospitals at their stations, if fit for the journey. Serious cases, unfit for the journey, were sent to the nearest military hospital in the direction of their stations, or if considered expedient to any military or civil hospital more conveniently situated. Detailed instructions, with a list of these hospitals, were furnished by the Deputy Director of Medical Services to the administrative medical officers of the various divisions. In all cases it was ordered that it should be ascertained by telegram beforehand whether accommodation was available. Sick reports were sent with all men reporting sick, and their kits, arms, rations, and blankets were directed to be sent with them to the reception hospitals. The reception hospitals were evacuated each day under the orders of the administrative medical officer of the division concerned. It was arranged that in the event of any cases of infectious disease occurring they should be transferred to the nearest civil infectious hospital, if no convenient military hospital was at hand. All railway arrangements for the evacuation of sick were made by the officers in charge of the reception hospitals under the orders of their respective generals. A railway ambulance coach to be attached to ordinary passenger trains was kept available for the conveyance of serious cases from the manœuvre area at convenient central railway stations, the names of which were notified by the Deputy Director of Medical Services. A medical officer for each division with two non-commissioned officers and two privates of the Royal Army Medical Corps and equipment (medical panniers, companions, haversacks, and water-bottles) were stationed to superintend the arrangements for the entraining of the sick on their transfer to military hospitals, the necessary arrangements for accommodation being made by the divisional authorities.

Ambulance Wagons.

Administrative medical officers of divisions arranged for the distribution of the ambulance wagons of the reception hospitals amongst the units on the line of march and in the field. On the line of march an ambulance wagon was detailed to proceed in rear of the second line of transport of each division. A motor ambulance wagon was placed at the disposal of the Deputy Director of Medical Services for the transfer of serious cases to hospital.

Miscellaneous Instructions.

Hawkers were not allowed to accompany the troops, who were forbidden to deal with them on the march or in camp. Special attention was directed to be paid to the care of the feet and the fitting of boots and socks. The regimental chiropodists were directed to attend at the medical inspection tents with the men of their respective units requiring treatment by medical officers for sore feet. It was noted that men of the Territorial Force (who are not supplied with the regulation pattern boots and who supply their own boots) in many instances wore pointed-toed boots, the result being that their marching powers were much impaired by sore feet and blisters.

Field Ambulances.

The Second Division, which mobilised at Aldershot up to its full war establishment, was complete with three field ambulances. The *personnel* was brought up to full war strength by calling out the army reservists and special reservists of the Royal Army Medical Corps. Many of these men had originally served in infantry regiments before joining the reserve, and, while their marching powers were good, it was thought that they were wanting in their knowledge of corps work. The non-commissioned officers detailed for the field ambulances might also have been better selected, and their powers of enforcing discipline were not as satisfactory as could be desired when one had to consider the class of men they had under their orders. Another remarkable feature of the medical mobilisation was the fact that while the infantry of the line were all provided with the new web equipment, the Royal Army Medical Corps were still wearing the obsolete forms of equipment whereby the greatcoat is carried behind strapped on the belt, causing severe abdominal strain and fatigue. The men felt themselves very much handicapped by this, and it is hoped that the medical authorities at the War Office will adopt the new web equipment which has proved so satisfactory, from a physical efficiency point of view, amongst the infantry. It seems peculiar that the medical branch of the army should recommend this new equipment for all other infantry units and omit its adoption in its own branch. The field ambulances worked well on their trial as far as their equipment went, but there was a marked tendency for the equipment of the different sections to get mixed up in camp.

Reservists.

Two classes of reservists were mobilised with the Second Aldershot Division, army reservists and special reservists. It was noted that many of the former were men of more or less advanced life and unfit for the arduous daily marching; many more suffered from advanced dental caries. Amongst the special reservists the opposite extreme was notable; many of these were mere boys and quite physically unfit to march the distances covered by the troops. In one column alone some 250 reservists were reported as having been so incapacitated by the marching that it was found necessary to transfer them to the Base Hospital at Aldershot. Such an occurrence as this becomes all the more grave when it is considered that the climatic and other conditions under which the army manœuvres occurred were so favourable. The weather was all that could be desired and the marches were not excessively long, the rations were generous, and tents were used almost every night. What would have been the experience under adverse conditions?

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Health of Birmingham.

THE report of the medical officer of health for the third quarter of the year shows that there were 3667 births registered during that period, as compared with 3814 in the previous quarter and 3724 in the third quarter of 1909. The births were equal to a rate of 25·8 per 1000, which was considerably below that of the third quarter in any previous year. The mean birth-rate for the third quarter in the ten preceding years was 30·3 per 1000. There were 1763 deaths, equal to a rate of 11·2 per 1000, which was considerably lower than in any quarter in any previous year. The mean death-rate for this quarter in the preceding ten years was 16·4 per 1000. The low mortality was largely due to the diminished number of deaths from summer diarrhœa. All the other infectious diseases, as well as phthisis and bronchitis and pneumonia, also showed a reduced mortality. The infant mortality was at the rate of 107 per 1000 births, as compared with 145 at the same time last year and an average of 203 in the third quarter of the ten preceding years. This infant mortality rate was quite the lowest ever recorded for this quarter.

Orthopædic and Spinal Hospital.

The annual report gives the following record of work during the year: Attendances, 15,019; new cases, 1478; operations, 665; in-patients, 382; country patients, 637. The number of operations had increased by 230 in 12 months—that is an increase of 50 per cent. The medical committee again emphasises the hygienic deficiencies of the present building. The hospital, although one of the oldest established in Birmingham and although requiring the most modern and up-to-date means for the surgical treatment of patients, remains housed in a building which can recommend itself to no one for the purpose for which it exists. This hospital, and no other in the city, devotes a large amount of its income to the supply of instruments and apparatus for the relief of lameness and general deformities. The financial statement showed: Subscriptions, £1124; donations, £147; supernumerary tickets, £228; hospital collections, £388; dividends and interest, £137. The expenditure, including

£653 for instruments supplied to patients, was £3124, being £1032 in excess of the income.

Stratford-on-Avon Hospital.

The annual report presented at the eighty-eighth annual meeting on Oct. 10th showed that the year closed with a credit balance of £77, the expenditure being £1844 as compared with £1808 last year. During the year 276 in-patients were treated, of whom 73 were medical, with a mortality of 8; 188 surgical, with a mortality of 6; and 15 ophthalmic. There were 153 operations under anæsthetics. A discussion arose on a proposal to appropriate a sum of £500 from the capital fund for building, alterations, and extensions. Several members objected to the capital being interfered with. The total cost of the alterations was given as £1600, and Mr. W. B. Gibbins generously promised £1000 if the work was started at once.

Birmingham Hospital Saturday Fund.

The total amount of this year's collections is £20,167 17*s.* 11*d.*, an increase of £478 10*s.* 7*d.* over last year. The President, Alderman Sir Hallewell Rogers, at a recent meeting made the interesting announcement that the Fund was shortly to embark on the management and maintenance of a consumptive sanatorium. Plans were being considered for a building to contain 50 patients to be erected on Romsley Hill, about eight miles from Birmingham. The site is an ideal one, well wooded, and 800 feet above sea level.

St. Luke's Guild.

At the invitation of the Dean of Worcester (Dr. Moore Ede) the members of the Birmingham and Midland Ward of the Guild of St. Luke held their festival on Oct. 18th at Worcester for the first time, previous visits having been paid to Birmingham, Coventry, Warwick, and Leamington. Dr. H. Cameron Kidd, of Bromsgrove, the master of the ward, presided at the annual meeting at the Deanery. Subsequently the members in their academical robes attended service at the Cathedral, the sermon being preached by the Dean.

Nov. 1st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Presentation Portraits to Sir James and Lady Barr; Complimentary Banquet.

Sir James Barr and Lady Barr were presented with their portraits painted in oils by Mr. Hall Neale at a banquet given in their honour by the subscribers to the Portraits Fund at the Adelphi Hotel on Oct. 25th. The committee was comprised entirely of members of the medical profession, Mr. F. T. Paul being the chairman, Mr. T. H. Bickerton honorary treasurer, and Dr. W. Blair Bell and Dr. R. J. M. Buchanan honorary secretaries. The function was a conspicuous success and was attended by 155 ladies and gentlemen. Mr. Paul, in an eloquent speech, bore personal testimony to the many striking qualities of Sir James Barr. He described him not only as a most scientific and resourceful physician and a valuable colleague, but also as a staunch friend and charming companion. He referred to various undertakings, civic and professional, that he had carried to a successful issue; especially emphasising the enormous amount of work he had done in connexion with the British Medical Association. In a sketch of his career, Mr. Paul alluded to Sir James Barr's numerous publications, and called special attention to his treatment of typhoid fever, and to his researches into the pathology of the circulatory system. He paid a tribute to Sir James Barr's generosity to the younger members of his profession, and to the encouragement he had given by his sympathy and support to scientific research. The chairman, in a happy vein, referred to the devoted help Sir James Barr had received from Lady Barr, who was deservedly beloved by all who knew her. He had the greatest pleasure in proposing the toast of "Sir James and Lady Barr." The toast was seconded by Sir Rubert Boyce, who expressed his admiration of Sir James Barr's courage and strength of mind in advocating many righteous causes and not fearing to hit out, even to his own detriment. Sir James Barr responded to the toast with much feeling, giving a brief account of his career which was full of interesting episodes. He spoke of the great kindness he had always received from members of the medical profession, and of the share Lady Barr had had in any success he might have attained. The toast of "The Ladies," proposed by Dr. William Permewan in a speech very happily phrased, was responded to by Mrs. F. T. Paul. The toasts of "The Artist" and "The Chairman" were also heartily received. Sir James and Lady Barr subsequently held an informal reception, which was attended by all who had been present at the banquet.

St. Luke's Day Medical Service.

The annual medical service (St. Luke's Day) was held at St. Luke's Church on Sunday, Oct. 23rd. The preacher was Dr. Paget, the Bishop of Oxford. There was a large attendance of members of the profession residing in Liverpool and environs. Academic costume was generally worn. The service was also attended by a goodly muster of the Royal Army Medical Corps (Territorials). The gallery was well filled by nurses from the various city hospitals. Several lady members of the profession were also present in academic costume. The collection will, as usual, be devoted to the British Medical Benevolent Fund.

Health Notes.

Dr. E. W. Hope, medical officer of health, speaking on Oct. 20th at the annual dinner of the Liverpool Cowkeepers' Association, said that of the thousands of samples of milk taken in the city last year not one was found to be affected with tuberculosis.—Alderman Menlove, the chairman of the health committee, stated on Oct. 20th that, judged by the statistics of the months which had already passed, the present year promised to return the lowest death-rate on record for Liverpool.

Death of the Medical Officer of Health of Birkdale.

Mr. Albert Victor Wheeler, of Scarisbrick New-road, Southport, for many years the medical officer of health of Birkdale, died at his residence on Oct. 21st. Mr. Wheeler, who was appointed medical officer of health in 1887, was 61 years of age.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Society of Medical Officers of Health.

AT a meeting of the South Wales and West of England branch of the Society of Medical Officers of Health held at Cardiff on Oct. 28th, Dr. D. J. Morgan (Swansea), in his presidential address, dealt with the subject of popular education on matters of hygiene. He maintained that the duty of a medical officer of health should consist not merely in carrying out the requirements of the law, but should have for one of its main objects the real education of the general public in all matters relating to health. The process of education should apply first of all to the Board of Education itself, secondly to the various examining bodies of the country, thirdly to the school teachers, fourthly to the school children, fifthly to the children's parents, and lastly to the general public. Referring to the medical inspection of school children, he deplored that many teachers had failed to realise the importance of a sound, healthy body in a young child. Such teachers must be taught that the first essential in life is a healthy body, and that children who are unhealthy are not merely a source of danger to other children but are in such a condition that they are unable to absorb knowledge to the best advantage. The children should be taught what health really meant in order that they might be able to bear the strain of later life.—The action of the Radnor county council in seeking to appoint a county medical officer of health and school medical officer at a combined salary, to include travelling expenses, of £350 per annum was adversely criticised, and a resolution was unanimously passed disapproving of the inadequacy of the salary offered.

Swansea and Merthyr Joint Asylum.

After negotiations which have been spread over a long period an agreement has at length been arrived at to provide an asylum for the boroughs of Swansea and Merthyr Tydvil. It is to be situated in or near to Swansea, and the initial cost of the land, buildings, and furnishing is to be defrayed

as to two-thirds by the corporation of Swansea and as to one-third by the corporation of Merthyr Tydvil. The management of the institution is to be in the hands of a committee of 25 persons, of whom 13 will represent Swansea and 12 Merthyr Tydvil. The population of Swansea at the last census was 94,514 and of Merthyr Tydvil 69,227.

Security of Tenure of Medical Officers of Health.

The medical officer of health of Newport (Mon.), Dr. J. Howard-Jones, has hitherto held office for a limited period, but at a recent meeting of the local authority he was elected without reference to time and can now only be called upon to resign his office with the consent of the Local Government Board. The medical officers of health of Cardiff city, the Rhondda and Aberdare urban districts, and the Llandaff and Dinas Powis rural district hold office on the same terms.

Abergavenny Workhouse.

The architect of the Local Government Board has given an estimate for the cost of providing a new workhouse at Abergavenny for about 200 inmates and cottage homes for 20 children, but the guardians take no steps in the matter. The Local Government Board has now sent an ultimatum to the guardians that if no action is taken the only alternative appears to be to dissolve the board of guardians.

Chalets for Consumptives at Swansea.

Joint action has been taken by the Swansea corporation and board of guardians for the treatment of consumptive patients. It is proposed to erect on land in the vicinity of the workhouse twelve chalets at a cost of £250. The cost of these buildings and of administering the institution will be divided equally between the corporation and the guardians. The patients admitted for treatment will not necessarily be paupers.

Swansea Slaughter-house.

It is so constantly asserted by the opponents of public slaughter-houses that the latter can only be carried on with the assistance of the rates that it is of interest to learn from the annual report of the Swansea public auditors that the net profit on the slaughter-house in that borough for the year ending March 31st, 1910, after providing one year's interest on stock and sinking fund, amounted to £564, an increase of £317 upon the profits of the previous year.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University: Rectorial Address.

THE Right Hon. George Wyndham, M.P., Lord Rector of Edinburgh University, delivered his rectorial address to the students on Friday, Oct. 28th, in the McEwan Hall. The chair was occupied by the Lord Chancellor of the University, the Right Hon. A. J. Balfour, M.P., and he was accompanied to the platform by an unusually large and representative gathering, while the hall was well filled. The Lord Rector took as the theme of his address "Romance: What it Meant and When it First Came into the Literature of Europe." The address was erudite, scholarly, and closely reasoned, and was listened to with much attention and interest by the bulk of the audience, but some of the finest passages were marred, if not lost, by recurring noisy demonstrations from the top gallery. After the address Mr. Wyndham inspected the Officers' Training Corps in the quadrangle of the University.

Edinburgh Students' Union.

The Edinburgh Students' Union has attained its majority, having been in existence for 21 years. This interesting fact was honoured by the presence of the Lord Chancellor of the University, the Lord Rector of the University, Sir William Turner, the Principal, Sir R. Finlay, and others at a luncheon in the Union after the Lord Rector had delivered his address. The toast of "The Union" was proposed by the Lord Chancellor, who spoke of the position the Union had attained and of its value in the life of the student. In the evening there was a torchlight procession.

St. Andrew's Ambulance Association.

The Earl of Dalkeith, President, occupied the chair last week at the annual general meeting of the St. Andrew's Ambulance Association, which was held in the Merchants' House, Glasgow. The annual report showed that during the year 7947 calls were made on the wagons of the association, and the total number of patients conveyed since the formation of the association is now 107,897. In Glasgow alone the calls numbered 5077, which, leaving Sundays out of the calculation, gives an average of 16·22 turns-out daily. Of these calls 2428 were to accidents and 2649 to cases of illness. The association during the year conducted and examined 572 classes in "first-aid to the injured," and 55 in "home nursing and hygiene." Certificates of proficiency were issued as follows: First-aid, 5936; nursing, 793; re-examination vouchers, 429; junior first-aid, 444; total, 7602; making a grand total since the formation of the society of 95,524. At the meeting, Sir George T. Beatson moved that a Provisional Order be applied for by the association to enable it to transfer the Red Cross Fund held by it to the Scottish branch, British Red Cross Society, with the exception of a sum of £3500, part of the said fund, which is to be retained by the association to enable it to carry out obligations already undertaken, including those under the sanction of the War Office.

Aberdeen City Hospital: Inauguration of Extensions.

The extensions recently completed in connexion with the Aberdeen City Hospital were formally opened on Oct. 26th by Lord Provost Wilson in the presence of a large number of medical men and others from the city and district. Councillor Kendall Burnett, convener of the public health committee, presided, and in his introductory remarks stated it was now 33 years since the original hospital erected on the same site was opened. Previous to that time accommodation had been found for small-pox in a disused match factory at Mounthooly, which the town council had been forced to secure, owing to the Royal Infirmary refusing to take the small-pox cases. The site for the present hospital was acquired in 1873 at a cost of £2500 from the University of Aberdeen. The hospital as originally erected cost, exclusive of site, about £12,000. It had accommodation for 50 patients. In 1887, owing to a threatened epidemic of small-pox, a wooden pavilion was hastily run up at a cost of about £800. This pavilion was still in good condition. In 1893 large extensions were undertaken. Two of the four original pavilions were doubled in size; the accommodation for nurses and the kitchen accommodation were also enlarged. These additions were completed in 1900, and cost about £28,000. They raised the accommodation for patients to 126, with an allowance of 2000 cubic feet for each bed. Owing to the rapid growth of the city, necessity rose of making accommodation for a large number of cases formerly treated in the Royal Infirmary; and owing to a more extensive use of the city hospital for the isolation of zymotic cases it was felt two years ago that a further extension should be made. It was this extension, the cost of which was expected to amount to nearly £16,000, which was being opened. The total number of beds for patients would now be 184. This would provide about one bed for every 1000 of the population. Edinburgh, with a population about twice that of Aberdeen, had a fever hospital with 652 beds, while Glasgow, with a population of 850,000, had fever hospital accommodation for 1100 patients, exclusive of a proposed new small-pox hospital intended to accommodate from 200 to 300 patients. It could not, therefore, be said that Aberdeen was even now extravagantly provided with fever hospital accommodation. During the ten years preceding the year 1908 the average number of cases treated in the hospital was 733. In 1908 it had risen to 1346, and in 1909 it was 1213. The mortality among scarlet fever cases in the Aberdeen City Hospital had been for many years one of the lowest of any large hospital in the kingdom. It was only about 1 per cent. for the last two years. Provision had been made for the suitable treatment of a few phthisical cases. This provision for open-air treatment would be serviceable in the treatment of other zymotics, for example, typhus fever. The annual expenditure at the city hospital amounted in the last financial year to slightly over £8000, exclusive of salaries. In Glasgow the total expenditure on their fever hospitals was over £95,000, and in Edinburgh it was fully £45,000. In proportion to population, the expenditure on fever hospitals in Glasgow and Edinburgh was last year about twice that of Aberdeen. The Lord Provost, in declaring the buildings open, referred to the good done by the preventive work carried on by the public health committee. The party afterwards inspected the various buildings, and expressed

admiration at the thoroughly complete manner in which they were equipped.

Dundee Town Council and Fever Hospital Enlargement.

A meeting of the Dundee town council was held on Oct. 27th to consider the state of affairs as regards infectious disease, and particularly scarlet fever and diphtheria, in the city as disclosed by Dr. C. Templeman, the medical officer, in his report. The erection of a temporary building to cost £2100 was recommended by the public health committee, and the council in committee first discussed the matter and subsequently made it a town council decision. In the course of discussion it transpired that the number of cases treated at King's Cross had grown from 171 three years ago to 657 this year. Questioned as to the council's liability if they refused to take in scarlet fever cases, the town clerk stated that the law was not clearly defined in the matter. There were no decided cases, but the Local Government Board was advised by Crown counsel that local authorities were bound to provide hospital accommodation for infectious cases, or at least for all infectious cases where proper isolation could not be got at home. In reply to other questions, the medical officer stated that he did not think he would be justified in refusing a case recommended by a medical man, and that it would be impracticable for the corporation to treat cases in their own homes. It was ultimately resolved to erect a temporary building at a cost of £2100, and that power should be given to the committee to proceed with the work.

The Premier in Aberdeen: Rectorial Address.

The Right Hon. H. H. Asquith, as Rector of Aberdeen University, visited Aberdeen on Oct. 24th and 25th. On the 24th he was entertained by the Senatus to dinner, and thereafter viewed the torchlight procession from the windows of the hotel. On the 25th he delivered his rectorial address in the Mitchell Hall of Marischal College, referring in the course of it to the growing tendency to specialism, which had become a marked feature of university work, both in Scotland and in England, during the past 50 or 60 years. This was to the good in so far as it tended to promote erudition and accuracy, at the expense of that which was merely superficial and smart; but the advantage was purchased at an excessive price if it were gained by the sacrifice of width of range and catholicity of interest. A university which was content to perform the office of a factory of specialists was losing sight of some of its highest functions. The man whom the university ought to turn out as its finished product at the end of his university course ought to be in Bacon's own phrase "a full man." Riotous proceedings on the part of the students took place afterwards, in the course of which the carriage intended to convey Mr. Asquith from the University to the residence of the Principal was completely wrecked.

Royal Aberdeen Hospital for Sick Children: New Building Scheme.

As already stated, it has been decided to erect a memorial hospital to His late Majesty King Edward VII., and a special appeal has been issued on this behalf. The Royal Aberdeen Hospital for Sick Children has now been working for 34 years. From a small beginning in the autumn of 1877, with 14 beds, the hospital has so grown in usefulness as now to be regarded as a district institution for the North-east of Scotland. Year by year the number of children has risen steadily until, with a limited accommodation of 80 cots, the hospital is unable, through lack of space, apart from the inconveniences and difficulties of the present buildings, to cope with the demands upon its accommodation, many ailing children having unfortunately to be turned away. The hospital has always secured the deepest interest and the general support of the most prominent citizens, but this cannot make up for the notable defects of the present building. Never designed for a hospital—a makeshift from the start—it is now hopelessly out of date, and the time has come when the increasing demands of an ever-growing city and wide surrounding district indicate that a larger and more efficient building must speedily be provided wherein to carry on the work. To be at all adequate the new buildings will require to contain at the very least 100 beds, and it is estimated that the erection of such a building, capable of ready extension for future requirements on a suitable site, will cost from £30,000 to £35,000.

Nov. 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The School of the Royal College of Surgeons in Ireland.

THE School of the Royal College of Surgeons has recently had cause to fear the rivalry of the various new State-endowed schools, being itself the only self-dependent school of medicine in Ireland. Attempts were made to enlist the sympathy of the Government with the view of obtaining relief as a direct grant. These attempts failed and a somewhat dismal outlook faced the school. A method has been found, however, by which help has been obtained from Government sources. The Department of Agriculture and Technical Instruction has agreed to recognise a certain number of courses in the school as courses in technical instruction, and to pay a small capitation grant. It is expected that the contribution this session will come to about £1000, and in future it may be more. This grant is, of course, not very great, but it will give considerable relief to the finances of the school.

Pasteurised Milk in the South Dublin Union.

Some weeks ago a report was presented to the South Dublin guardians which reflected on the use of pasteurised milk in the nursery.[1] The guardians thereupon directed the medical officer in charge of the nursery, Dr. F. J. Dunne, upon whose advice pasteurised milk had been introduced, to report upon the condition of the nursery. At their last meeting, without waiting for Dr. Dunne's report, the guardians decided forthwith to give up the use of pasteurised milk and to return to the use of fresh cow's milk. It was pointed out by certain guardians that the question of diet was in the main a medical question, and that it would be wise to wait for Dr. Dunne's report, but a majority of the guardians thought otherwise. This decision is unfortunate, as it looks as if for some reason inquiry is being avoided, and this on a subject which has much exercised the public.

Conferring of Degrees at the National University.

The first public conferring of degrees in connexion with University College, Dublin, took place last Saturday, the Vice-Chancellor of the University, Sir Christopher Nixon, presiding. In his address the Vice-Chancellor drew attention to the insufficient provision made for building in connexion with the National University. It is stated that only a sum of £40,000 is available at present, and Sir Christopher Nixon claims that at least £200,000 is required. It was an unpleasant feature of the ceremony that both the Vice-Chancellor's address and the actual conferring of degrees were interrupted by the rowdyism of a certain number of the students.

Corporation Grants to the City Hospitals.

For some time back the question of the contributions of the Dublin corporation to the city hospitals has been under consideration, as it has been suggested that the poor of the city are not obtaining the corresponding benefits to which they are entitled. At the meeting of the finance committee Councillor Quaid, with the object of effecting, if possible, a reduction in union infirmary expenditure, "which had increased enormously owing to the exclusion of large numbers of Dublin people from the city hospitals," said it would be desirable to have a conference between the finance committee and the boards of the North Dublin and South Dublin unions with a view of formulating a scheme for the revision of the grants or for a more efficient application thereof by a system of capitation fees. This conference has since been held, but the results have not been made public. No representation has been made to the Dublin hospitals, but the charge that the hospitals exclude city for the sake of country patients seems to have no proof in fact.

Election of a Direct Representative to the General Medical Council.

The election of a Direct Representative for Ireland to the General Medical Council is to take place in January next. Dr. Leonard Kidd of Enniskillen is the present representative, having defeated the late Sir William Thomson in 1906, and he has announced his intention of again seeking election. Up to the present there is no suggestion of any other candidate being put forward.

[1] THE LANCET, Oct. 8th, p. 1106.

Irish District Councils and the Medical Profession.

In reference to the appointment of an inspector under the Dairies and Cowsheds Order, the Cookstown rural council had a motion some time ago before it to appoint a veterinary surgeon for the whole union at £50 per annum, but an amendment was carried to offer the positions to the dispensary medical officers at £7 10*s.* each, while the previous salary had been £15. At the weekly meeting on Oct. 22nd replies were read from the dispensary medical officers all refusing the offer, their reason being the inadequacy of the salary, which, it was stated, would not pay posting expenses. Two notices of motion were then handed in, one to appoint a veterinary surgeon for the whole district at a salary of £30 for a year, the other to the effect that the medical officers be reappointed at the old payment of £15 each for the year. The whole discussion and extraordinary action of the Cookstown rural council indicate the need of a reformed State Medical Service.

County Antrim Infirmary.

At a meeting of the Ballymena board of guardians held on Oct. 29th the replies from the various dispensary medical officers of the district regarding whether they approved of sending patients for special treatment to the Co. Antrim Infirmary, Lisburn, were considered. Of these nine replies, one, not having sent any patients, could not form an opinion of the usefulness of the infirmary, and one saw no objection to sending patients to the Lisburn Infirmary provided the necessary specialists were on the staff and always available in cases of sudden emergency. The remainder were against sending patients to the Lisburn Infirmary, either because of its distance or because they preferred sending special cases to special hospitals in Belfast. It was agreed by the guardians to send a patient requiring special treatment to the Lisburn County Infirmary, as they had to consider how to get some return for the £117 they subscribed towards upkeep.

Annual Dinner of the Cork Medical and Surgical Society.

The annual dinner of the Cork Medical and Surgical Society, recently held at the Imperial Hotel, Cork, was a distinct success. Dr. John Booth, the President, occupied the chair. After the toast of "The King" had been duly honoured, the Recorder of Cork proposed the toast of "The Cork Medical School." Professor H. Corby and Dr. P. T. O'Sullivan having replied, the President proposed the toast of "The Army and Navy," to which Colonel Dodd replied, and the toast of "The Guests," coupling the toast with the names of Dr. P. J. Macnamara of Kilmallock, and Mr. Barry Galvin, legal adviser to the Cork Corporation. Mr. Philip Lee proposed the health of the President.

Nov. 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Disastrous Fire at the Toulouse Faculty of Medicine.

A GREAT part of the buildings of the Toulouse Faculty of Medicine was destroyed by fire on Oct. 27th. In the morning smoke was seen to be coming from under the roof, the whole of which was soon burning furiously and fell in, the conflagration being aided by a high wind which was blowing at the time. The great library was entirely destroyed, but the laboratory escaped. Of the first floor and the superstructure nothing now remains; the ground floor and the principal front have also suffered greatly. The physiological amphitheatre, the large room used by the professors, the dean's office, the secretary's office, and other portions of the administrative department have quite disappeared, but the great amphitheatre and some outlying portions of the main edifice have not suffered at all. Buildings which have cost 880,000 francs are for the most part reduced to ruins. The structural damage amounts to about 450,000 francs, and, including the value of the library, the total loss will be nearly 1,000,000 francs. The fire is believed to have been caused by an electrical short-circuit.

The Mental Aberration of King Charles VI. of France.

At a meeting of the Academy of Medicine held on Oct. 25th M. Dupré made a communication on the subject of the mental condition of King Charles VI. of France. He said that this monarch, who suffered from inherited psychical defects, was of only moderate intelligence and low mental stability, and that for 30 years he had from time to time attacks of insanity alternating with lucid intervals; during these intervals, however, he was able to resume his position and duties as head of the State. His mind began to fail at the age of 24 years, some months after an illness which was probably typhoid fever, the first symptom of mental disorder being the celebrated attack which he had in the forest of Le Mans. An examination of the clinical features of this attack showed the association of maniacal excitement with confusional delirium.

Citrate of Soda in the Vomiting of Suckling Infants.

At a meeting of the Academy of Medicine held on Oct. 18th M. Variot described his investigations and his numerous observations on the beneficial action of citrate of soda in the vomiting of suckling infants. He said that this remedy, which was already in general use, ought to be given in doses of 1 or 2 grammes daily. Whether the vomiting be due to insufficient nourishment or to over-feeding, the administration of citrate of soda was in either case beneficial.

Oysters.

Speaking at a meeting of the Academy of Sciences on Oct. 24th M. Henneguy gave an account of some experiments which had been made with oysters kept in contaminated water. It was found that oysters which had lived in such water from the earliest stage of their existence became wholesome when transferred to filtered sea-water for a week or two. The sea-water used in connexion with the laboratory at Concarneau was filtered through thick layers of sand, and the oysters kept in this water did not deteriorate in either quality or flavour.

A New Symptom in the Diagnosis of Pulmonary Lesions.

At a meeting of the Academy of Medicine held on Oct. 18th M. Hirtz described a very important sign which will be of considerable assistance in the diagnosis of certain thoracic lesions. After having percussed the chest while the patient was breathing in the normal manner, he percussed it again whilst the patient was distending the thorax by a prolonged inspiration. If an area of dulness observed in the first percussion disappeared in the second one the inference was that the dulness was due to a pulmonary lesion and not to pleural effusion.

Sleeping Sickness.

M. Roux, director of the Pasteur Institute, presented to the Academy of Sciences on Oct. 24th a report on the researches of M. Roubaud, who has found that the trypanosoma, which was the cause of sleeping sickness, perished in seasons of drought, even in the proboscis of the tsetse fly by whose bites the disease was propagated.

Oct. 31st.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of the Syphilitic in Rome.

Professor Ciarrocchi, the well-known dermatologist and medical director of the Hospital of San Gallicano, has furnished me with the following particulars regarding the institutions existing in Rome for the treatment of persons suffering from syphilis. These institutions are of two kinds—namely, hospitals for the reception of the severer cases, and dispensaries or "ambulatorii" for those who are able to be up and about and do not require rest in bed. The Hospital of San Gallicano, founded in 1724, is that which receives the great majority of the former class of patients. It is an interesting old building in the Trastevere district of Rome, within a short distance of the Tiber, and in its large, lofty, well-ventilated wards affords accommodation for 250 beds, of which 150 are devoted to the reception and treatment of venereal cases, the remaining 100 beds being chiefly reserved for the victims of ringworm, a disease very prevalent amongst the peasantry in the Roman Campagna. This hospital forms part of the "Opera Pia degli Ospedali Riuniti di Roma," an independent and autonomous organisation with its own endowment. In the case of syphilitic patients, however, the organisation receives a subvention from the State, amounting to about 3 lire (2*s.* 5*d.*) per diem for each venereal patient treated at San Gallicano, in consideration of

the latter's utility in restricting the spread of syphilis. From 1500 to 2000 of such patients are received and treated in its wards every year. A limited number of syphilitic cases is received into the dermo-syphilopathic department of the Policlinico, which has about 50 beds at its disposal for this object, but these patients are taken in only for teaching purposes, and are small in number, funds not permitting of more than a few of the beds being so occupied. Persons suffering from syphilis affecting special organs are also received into many other hospitals in the city—those, e.g., with uterine forms into the Obstetrico-Gynæcological Clinics, those with ocular forms into the Opthalmological Clinics, and so on. In San Gallicano, as well as in the other Roman hospitals, patients with venereal complaints are placed in the ordinary wards more or less together with those suffering from ordinary diseases, the strictest precautions being at the same time observed to obviate any possibility of contagion, whether moral or physical, being conveyed to the latter. The absolute segregation and isolation of the syphilitic insisted upon in the past are no longer practised, having yielded unsatisfactory results. But the greater number of syphilitics, those, namely, that do not require to remain in bed, are treated at the Syphilitic Dispensaries ("Dispensarii Celtici"). Of these, there is one at San Gallicano itself, one at the Hospital of St. Antonio, a third at the dermo-syphilopathic department of the Policlinico, and six others in the various centres of the city. Each dispensary has its own medical director and one or two medical assistants whose duty it is to give consultations every day for two hours, in some dispensaries to men and women on alternate days, in others to both sexes indiscriminately on the same day, according to the accommodation available. Medicines are supplied gratuitously to the very poor, semi-gratuitously to others. Those dispensaries which are attached to the hospitals receive subsidies from the State, but the others are entirely supported by the State. The average daily number of patients treated at each dispensary is about 100. Following ancient tradition, some of the pharmacies put a room at the disposal of medical men for the treatment of dispensary patients, but there are no means of estimating the numbers of these. The routine treatment of the disease consists in the hypodermic injection of preparations of mercury, either in soluble or insoluble forms. Finally, for the army there is a special hospital for venereal diseases, that of Santa Croce in Gerusalemme. For the supervision of brothels and of prostitutes in Rome the law provides a special sanitary service under the control of the Government.

Early Recognition in Italy of the Infectiousness of Phthisis.

It is well known that the infectious nature of pulmonary phthisis has long been recognised in most of the Latin countries. This was more particularly the case in Italy, where, indeed, stringent laws have from time to time been enacted prescribing rigorous measures against its spread. For example, in 1754 the magistrate of public health of Florence decreed that each physician of the Grand Duchy of Tuscany should be obliged to denounce to the Tribunal of Public Health in Florence, and to the government commissioners and judges in the other provinces, any case of confirmed consumption under a penalty of 100 scudi; and later Ferdinand of Naples issued a decree ordering the destruction by fire of the clothing and effects of all persons dying from consumption. That a law was in force under the Papal government in Rome early in the last century would appear from the account given by Joseph Severn, the devoted friend of John Keats, in letters written before and about the time of the latter's death and now preserved in the Keats-Shelley Memorial House in the Piazza di Spagna in that city. Here is an extract from one of these dated Jan. 11th, 1821, addressed to Mrs. Bawne: "..... but the inhumanity, the barbarism of these Italians! So far I have kept everything from poor Keats, but if he did know but part what I suffer from them and their cursed laws, it would kill him. Just to instance one thing among many. News was brought me the other day that our gentle landlady had reported to the police that my friend was dying of consumption. Now their law is that every individual thing, even to the paper on the walls of each room the patient has been in, shall without reserve be destroyed by fire, the loss to be made better than good by his friends." Again, after Keats had died, and poor Severn was suffering from the effects of his unremitting devotion to his friend whom he had nursed single-handed during the last short weeks of his life, comes another outburst of wrath in a letter written on March 3rd, 1821: "These brutal Italians have nearly done their monstrous business—they have burned the furniture—they have done their meetings—and I believe, at least hope, no more of these cursed cruelties will take place"; and, again, "On the head of my partial collapse came an unlooked-for annoyance. The vile indiscriminating Roman law required that all the furniture should be burned and the rooms refurnished and every way restored. In this new disaster Dr. Clark [the eminent physician, afterwards Sir James Clark] was a true friend in need, and managed to reduce the charges to one-half the amount demanded from me. The whole affair was most distressing and shameful." And finally he writes: "The burning of the furniture took place in the Piazza di Spagna. Then the walls were all done up afresh." I may add in connexion with this burning of Keats's furniture that the caretaker of the Keats-Shelley Memorial House has heard the story of it from his mother, who was an eye-witness of the occurrence, which took place in the public square in the presence of a crowd of onlookers. The unfortunate victims of consumption and their friends must have suffered great hardships in these times, and Severn's strong language will, under the circumstances, be excused even by the objects of his anger. But at the same time the Italians have some reason to pride themselves on the early application in their country of these really enlightened if Spartan measures which later knowledge of the etiology of phthisis has shown to be largely warranted, and which are being adopted to-day by every civilised country, although no doubt in a milder and less oppressive form than they we apt to assume in that ruder epoch.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Scopolamine-Pantopon Narcosis.

Dr. G. Brüstlein, assistant surgeon at the Inselspital in Bern, has just published a paper on the use of pantopon and scopolamine to replace general chloroform or ether narcosis. Pantopon is a purified solution of opium. In a good many cases, especially strumectomies, the patients were walked in a semi-conscious condition into the operating-room and operated on without ether, though in some cases a small quantity of ether was still necessary. There was total absence of the feeling of suffocation, which is often distressing in ether narcosis. One and a quarter to one and a half hours before the operation one gramme of a 2 per cent. solution of pantopon was injected hypodermically; half an hour later the dose was repeated with the addition of 1/100 grain of scopolamine. Women only received one injection of pantopon, 2/3 grain, and 1/200 grain scopolamine. In over 100 cases this narcosis was followed neither by vomiting nor constipation. The solution must always be prepared just before use.

Centenary Celebration of the Medical Society of the Canton of Zürich.

On Oct. 19th the centenary celebration of the Medical Society of the Canton of Zürich took place. There was a meeting at the town-hall in Zürich, at which Dr. Hauser, the present chairman, who has just been appointed chief medical officer of the Swiss army, and also M. Lutz, member of the Government, made speeches. The banquet, attended by upwards of 300 medical men and their wives, took place at the town-hall, and many medical societies were represented. The leading medical journal of Switzerland, the *Korrespondenzblatt für Schweizer Aerzte*, whose editors are Professor Jaquet and Dr. von der Mühl of Basel, celebrated the occasion by issuing a double number containing a dozen valuable contributions by well-known medical men. Of these contributions I may mention the following: Professor Cloetta, on the Nature of the Diastole; Professor Eichhorst, on Infantile Alcoholic Neuritis; Professor Haub, on the Causal Treatment of Eye Diseases; Dr. Wilhelm Schulthess, on Scolioses and the School; Professor Silberschmid, on the Signification of Pathological Microbes; and Professor Wyder, on Early Rising after Childbirth.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Sunstroke and Insurance against Accidents.

A MAN recently sued a Hungarian accident insurance company under his policy on the ground that an attack of sunstroke from which he suffered was of the nature of an accident. The company, however, resisted the claim, pleading that sunstroke was not an accident but a disease, and that their policy holders were insured only against injury from unforeseen external violence. The word "accident" in the policy, from the company's point of view, was to be taken as employed in its ordinary sense—that is to say, as an occurrence not according to the usual course of things. It might certainly be by accident that a person became exposed to conditions leading to sunstroke, but the circumstances under which a person might be affected thereby ought to be classed, in the opinion of the company, among natural causes and natural phenomena, and these could not be correctly called accidents. The court decided in favour of the plaintiff, but the medical journals are not quite satisfied as to the justice of the decision. They say that if it is allowed to stand, then frost-bite, chilblains, and even "catching cold" would have to be placed in the category of accidents, and might be made the subject of claims.

The Treatment of Acne Rosacea by Tonogen.

In a recent article in the *Orvosok Lapja* Dr. Pór writes that the administration of digestive tonics and intestinal antiseptics is usually indicated in acne rosacea. In order to bring about the disappearance of the chronically dilated blood-vessels he has employed tonogen (an extract of the suprarenal gland) both as a topical and also as an internal remedy. The application of the extract to the affected area of skin for the first time determines slight transient hyperæmia, which is succeeded by pallor due to the contraction of vessels, but this hyperæmia is not usually observed after subsequent applications. Permanent improvement was observed by Dr. Pór within six weeks of the commencement of the treatment. The effects of the external applications were markedly enhanced by the simultaneous internal administration of the extract in doses commencing with one five-grain tablet thrice daily, gradually raised to six, the dose being reduced in the event of any unpleasant symptoms, such as giddiness or nausea. In cases of moderate severity the combined treatment proved very satisfactory, but it was sometimes found necessary to eradicate the enlarged vessels by the electro-cautery.

Variations in the Susceptibility of Guinea-pigs to Diphtheria Toxin.

At a recent meeting of the Medical Society Dr. Schiff, in speaking of the routine testing of the strength of diphtheria antitoxin, called attention to the usefulness of the antitoxin unit furnished by the Institute for Experimental Therapy under the direction of Professor Ehrlich. The one uncertain element was, he said, the relative resistance of the guinea-pigs to diphtheria toxin. It was found that different dealers furnished guinea-pigs of slightly different susceptibility, and on investigating the matter he discovered that the different degrees of resistance belonged to certain families or litters and were constant for those families. For instance, one mother gave birth to young which did not react to what was the usual fatal dose, and four successive litters possessed the same resistance. As each guinea-pig could be tested but once the precise degree of resistance could not be measured, but it appeared probable that this family could tolerate 40 per cent. more toxin when mixed with the antitoxic unit than those of average susceptibility. Other mothers were traced whose offspring possessed less resistance than the ones described, but could still neutralise 20 per cent. more toxin, when mixed with the antitoxin unit, than the average. Dr. Schiff said that experiments were now being made for the purpose of determining the part played by the male in the transmission of toxin resistance. In the case of the most resistant family, the four litters were the offspring of two males.

Paroxysmal Tachycardia.

Dr. Neress has reported an obscure case of heart disease which terminated fatally. The patient had had his attention called to his heart in boyhood by his medical attendant, and had always troubled himself about it. Attacks of fluttering, with changes in disposition, which varied with the character of the pulse, were the prominent features of the case. The physical signs were variable, signs of myocarditis with congestion of the liver and œdema of the feet gradually developing. There was no pain, but attacks of apparent angina occurred with fair frequency. At the necropsy fibrous myocarditis, sclerosis of the coronary arteries, and a thrombosis of the left ventricle were found. Many diagnoses had been made on this case, and it illustrated the great difficulty of recognising myocarditis in the early stage. Dr. Neress emphasised the importance of causing patients to make muscular efforts during the examination of the heart; a murmur which developed under such exercise was suspicious.

Oct. 29th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Cholera.

SINCE I wrote last cholera has made its appearance in the Ottoman metropolis. This was, of course, anticipated, considering the near proximity of Russia and the enormous difficulties which the medical authorities at Constantinope have to contend with in order to take the necessary measures of prevention. Then again, it is well-nigh impossible to prevent an epidemic spreading to Constantinople, a city of great commercial importance and of imperfect sanitary conditions Happily, however, the weather is cool at present. Up to now the disease has made little progress, one or two deaths occurring daily, seldom more. According to the official reports, since Sept. 13th, when the epidemic seems to have made its first appearance, to Oct. 12th, there were registered 84 cases, of which 46 died. One of the great difficulties which the medical and municipal authorities of the metropolis, as well as of the provinces, encounter in combating the spread of the epidemic is, as in Russia, the incredulity and ignorance of the lower classes of the population. A great many of them do not believe that there is any cholera in Constantinople, and refuse to take the prescribed measures of precaution, spreading at the same time the absurd news that medical men "invent" cases of cholera in order to be able to draw money from the Budget assigned to combat the epidemic. In the provinces the behaviour of the people is still worse. In Trebizond, for instance, a medical man was mobbed for trying to bring help to the cholera-stricken. As in Russia, so also in some parts of Turkey, the populace firmly believe that medical men poison the wells of drinking-water, thereby causing disease and death for selfish personal interests. The Sanitary Commission continues to take rigorous measures. All suspicious quarters are visited and sanitary improvements are introduced so far as is possible in Constantinople, with its dirty and narrow streets, and a drainage system so antiquated. All the vendors whose stands are unclean are being fined or otherwise punished. This is done, for instance, in quarters like Tatavla, a valley beyond, and to the left of, Pera, where the sanitary conditions are exceptionally bad. It has also been decided to increase the number of the municipal medical men so as to enable them to visit the houses of the poorer quarters. I understand, too, that it has been thought necessary to issue a proclamation warning the population against throwing any refuse from doors and windows—a deplorable practice which is very much resorted to at Constantinople. A local paper announces that the *tchoptchis* (refuse gatherers) will henceforward call twice daily, instead of once, at each house, and that the number of street sweepers will be considerably increased. In Bagdad and its neighbourhood cholera is spreading, and a case of the disease is reported from Belgrade. The administration of the Oriental Railway Company states that the Bulgarian Sanitary Council has decided that all passengers, infected or non-infected, travelling beyond Zaribrod may pass Bulgaria without quarantine, provided that they are kept in a special carriage and do not come in contact with any person in Bulgaria.

A New Hospital.

I understand that the municipality of Constantinople intends to erect a new hospital in the quarter of Shehir Emin, beyond Ak Serai, in Stamboul. The *Osmanischer Lloyd* says that the plans are ready, and that the construction will begin in the month of March. The expense of construction will amount to £T50,000, and will be drawn

from the city budget. After the completion of the institution the hospital of "Gureba-i-Musselmin" of Yeni Baghtche Tchair will be transferred to it. The new hospital will contain rooms for private patients who are able to pay. The "Gureba-i-Musselmin," a Moslem hospital, which was much neglected during the *régime* of Abdul Hamid, is receiving at present adequate attention under the chief medical officer, Dr. Hussein Ihsan Pasha. The wards, the barracks, the operation room, and the laboratory are being completely renewed. It can now accommodate 300 patients.

The Sale of Poisonous Drugs.

The attention of the medical and other authorities is again drawn to the fact that the public in Turkey have every facility for obtaining poisonous drugs without any medical prescription. In Constantinople, for instance, it is very easy to procure corrosive sublimate without prescription at the different *actars* (druggist shops) and at the *Missir Tcharshi* (the so-called Egyptian bazaar). In the provinces it is, of course, still worse, as the lack of control and supervision there is very great indeed. Often the most poisonous medicines are taken by ignorant people in incredibly large doses, with results that can easily be imagined. The other day a young woman was taken, in a state of complete collapse, into the Jewish hospital at Balat, on the right shore of the Golden Horn, and soon afterwards died there. Investigation revealed that she had obtained, in the Egyptian bazaar, a large dose of corrosive sublimate and had drunk it in order to procure abortion. She already had seven children, and dreaded a further increase of her family. It is necessary, therefore, that the authorities should take all possible measures and precautions against the indiscriminate sale of poisonous drugs.

Earthquakes in the Provinces.

In Salour, *vilayet* Diarbekir, a violent earthquake has caused much damage, numerous buildings being injured and a number completely destroyed. Happily, however, there was no loss of human lives. Also in the *vilayets* in the neighbourhood of Diarbekir, as well as in the province of Erzeroum, violent earthquakes occurred, but details of these are wanting as yet.

Miscellanea.

The Children's Hospital at Shishli, beyond Pera and Taxim, will receive the services of a special medical attendant with a salary of £T10 monthly, whose duty will be to apply the Roentgen-ray treatment.—The Ministry of War is sending this year 20 military medical officers to Germany to complete their medical studies there.—Under the presidency of Madame Rifaat Pasha, the wife of the Minister for Foreign Affairs, a Red Cross Society has been formed, which has now issued its statutes.—The Turks have formed an Ottoman Anti-Alcoholic Union with the purpose of combating the increasing consumption of alcohol among Moslems.

Oct. 13th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Ethnology in West Australia.

Two ethnological expeditions have begun operations in West Australia. One is organised from Cambridge, under the direction of Mr. Alfred Brown, and the other is a Swedish undertaking in the charge of Dr. Eric Mjoberg. This latter expedition will cost £1100, the funds being provided by the Stockholm Academy of Sciences. It will proceed to the north-west and operate from Derby up the Fitzroy River. The Cambridge expedition has a double object in a study of aboriginal features and the collection of botanical specimens.

Radium for the Poor.

In response to the appeal by the *Sydney Daily Telegraph* for public subscriptions to a radium fund the sum of £2021 has been received, including £1400 as the result of a special *matinée* performance and collection by Miss Nellie Stewart.

Remarkable Record.

Mr. Justice Chomley of Victoria has been granted a year's leave of absence. The judge has been in the public service for 57 years, and during the whole of that period has not had a single day's sick leave.

Private Hospitals.

A new Bill has been introduced in Victoria to regulate the conduct of private hospitals. The definition is, "Any house, building, tent, or place (other than those excluded) in which medical, surgical, or lying-in cases are received or lodged, or in which it is intended that they shall be received or lodged for treatment, attendance, and cure, for which a charge is made." All private hospitals are to be registered annually. The licence is issued by the Minister for Public Health on the advice of the Board, but the former has absolute power. Every private hospital must at all times have a resident manager, and this person must be subject to the approval of the Board. Registration books must be kept and official inspection is provided for. The managers are required to give information respecting certain diseases and in the case of illegitimate births to notify the neglected children's department.

Bush Nursing Scheme.

The scheme for extension of district nursing to country areas, which was formulated by Lady Dudley, has practically been abandoned. Meetings were held in Sydney and Melbourne, but it was apparent that financial support would not be forthcoming from the general public and that the feeling amongst medical men and nurses was that the proposed new order of nursing was not required.

Melbourne Hospital.

Dr. W. Moore, the senior surgeon at this institution, has resigned his position on the staff after a tenure of 25 years. Under the new regulations Dr. Moore might have continued to hold the position for many years so far as age limit is concerned, but he has stated that his object in retiring is to give the younger surgeons an opportunity of advancement. Dr. Moore has been one of the leading figures in the surgical world in Australia for the past 15 or 20 years. His training is entirely Australian and he has not visited any of the old world centres. Dr. Moore will continue to hold his seat on the committee and take an interest in the affairs of the hospital.

Health of Sydney.

The annual report issued by Dr. W. G. Armstrong, the health officer, sets forth that the population of Sydney is now 592,000. The birth-rate was 26·11 per 1000 of estimated mean population, and illegitimate births formed 10 per cent. of total births. The recorded death-rate was 9·83 per 1000, the fully corrected rate, however, being 11·09. Scarlet fever figures were low, but diphtheria was higher than any year since notification became compulsory. 22 persons were known to be attacked by plague, of whom 7 died. Some of these belonged to the crew of a visiting steamer. About 68,000 rats and 8000 mice were examined, and 136 rats and 11 mice were plague infected. The death-rate from tuberculosis was 0·83 per 1000 living. Infantile mortality rate was 81 per 1000 births, which was the lowest yet recorded. The Pure Foods Act came into force on July 1st, 1909, and has so far been administered by the Board of Health, no administrative power having been granted to any local authorities. Generally the amount of food adulteration disclosed was not significant.

Melbourne Fever Hospital.

The Infectious Diseases Hospital at Fairfield, a Melbourne suburb, has been a fruitful source of complaint and dissatisfaction. The Government called for a report from the Board of Health, and under this it is probable reforms will be undertaken. The building is quite inadequate, leading to constant overcrowding. The charges for maintenance are excessive and it is recommended that they be abolished altogether and the hospital supported by Government grants and direct municipal aid. These reforms will meet the chief objections, which have related mainly to such gross overcrowding as placing two children in one bed and to the injustice of compelling comparatively poor parents to pay 7*s.* 6*d.* per diem for each child treated.

Parkinson Memorial.

To perpetuate the memory of the late Dr. T. C. Parkinson, who died from plague accidentally contracted while engaged in research work for the Indian Plague Commission at Elstree, Herts, the Sydney University has decided to establish a Parkinson memorial prize. The prize will be awarded annually, and the subject of examination will be pathology.

Oct. 1st.

Obituary.

SYDNEY RINGER, M.D. LOND., F.R.C.P. LOND., F.R.S.,

CONSULTING PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

IN our issue of Oct. 22nd we announced briefly the death of Dr. Sydney Ringer, which took place at his country residence at Lastingham, Yorkshire, on Oct. 14th, in the seventy-sixth year of his age.

Dr. Sydney Ringer, in virtue of one of his books, possessed a name that is familiar to many generations of medical students, for the famous "Handbook of Therapeutics" ran through many editions, increasing in value and popularity to the end. His professional career was closely associated with University College Hospital, at which institution he held every post, and where he was at the time of his death emeritus professor of medicine. Like so many distinguished members of the medical profession Sydney Ringer was a Norwich man. Entering University College as a medical student, he took his earliest qualification in 1859 as Member of the Royal College of Surgeons of England and Licentiate of the Society of Apothecaries, the usual double qualification of that day. He was at this time 25 years old, and therefore a little senior to men of his class, which makes the fact that in the very year of his qualification he contributed a paper on Sound to the Transactions of the Royal Society more easily understood. In 1860 he matriculated in the University of London as M.B., proceeding three years later to the M.D. degree, in which year he took also the Membership of the Royal College of Physicians of London. He had at this time established quite a position as a medical writer, having contributed articles on Diabetes, Ague, and Scarlet Fever to the Transactions of the Medico-Chirurgical Society and also two articles upon Cardiac Murmurs to the *Edinburgh Monthly Journal*. In 1863 he was elected an assistant physician at University College Hospital, being also assistant physician at Great Ormond-street Children's Hospital, where he had filled the post of medical registrar, while he had worked also in Paris and at the Brompton Hospital for Consumption and Diseases of the Chest.

His election to University College Hospital gave him an opportunity of showing that he was an admirable clinical teacher. He would discuss any case that came before him in a systematic manner, contrasting the various symptoms in comparison with the maladies with which they might be associated, doing this, moreover, in a systematic and lucid manner and without any special preparation, which could hardly fail to be valuable to the students when the range of practical medicine with which he would deal came to be considered. His magnificent work in the out-patient department of the hospital gave him this close grasp of clinical medicine in all its phases. In addition to his learning and acuteness he had the great gifts of order and industry. Punctuality itself, he never was sparing of his time or of his energies, and was relentless in tracing to their first causes the meanings of any symptoms that presented themselves. This gave him a wonderful familiarity with any medical phenomena in whatever stage they presented themselves to his attention, and while allowing him to realise the difficulties which the students were feeling, enabled him also to meet those difficulties, both comprehensively and in detail, in the order in which he had taught himself to surmount them. University College Hospital was at that time a home of great clinicians. Walshe, Jenner, Parkes, and Reynolds, to mention four, in their several capacities were achieving high reputation by their interpretations of pathology and by the practical nature of the lessons they were able to base upon the solid foundation of their scientific equipment. Ringer, though his reputation as a clinician was largely overshadowed by the fame which he acquired as a pharmacologist, belonged essentially to their group, and generations of students are able to testify that they learned from his lips lessons of incomparable practical value while working in his wards.

Ringer was house physician to Dr. Parkes and his bent towards clinical medicine was greatly stimulated by the work of Walshe and Jenner. The fact that Ringer devoted himself at first to the pursuit of clinical medicine may perhaps be attributed to the influence of these teachers. All students of University College know what an exceptional clinician he was, how quick and accurate in observing and shrewd in the interpretation of symptoms, and how painstaking he was in comparing the findings of the post-mortem room with the observations and deductions made during life. He was also almost always engaged in investigating some point in clinical medicine or instigating others to do so. Thus some 25 years ago he caused one of his house physicians to make an extended series of observations on leucocytosis in various diseased conditions from the point of view of diagnosis, and later on was much interested in, and made many observations on, the significance of pulsation of the jugular veins. Clinical work absorbed a large portion of his time and energies, although the work that he did in the physiological laboratory of University College in pharmacology and physiology is that by which he will be remembered, more especially by those who did not come under his personal influence as a teacher of medicine. Ringer carried out numerous researches on the action of drugs and poisons on the functions of the body and was one of the first in this country to put pharmacology on a definite scientific basis, but important as this work was it does not compare with his really classical observations on the action of the inorganic bases such as calcium, potassium, sodium, &c., on the functions of living protoplasm. Ringer's observations on this subject were carried out by systematic experiments conducted during a long series of years with a marvellous degree of completeness and accuracy so that subsequent workers have found but little to add. He showed how the presence of these salts in small quantity was an essential of most forms of protoplasmic activity, and also how the members of one group tended to produce antagonistic effects to those of another group, and he illustrated this more especially in the case of potassium on the one hand and calcium on the other. These researches attracted the notice of physiologists at once, and from the time of their publication to the present their fundamental importance has been recognised more and more, and many of his results have now become the commonplaces of physiology. Ringer was a freely scientific physician with a very broad outlook so far as concerned the problems of living matter and possessed a fertile imagination which he controlled in all his work by the most rigid experimental tests.

We have endeavoured in this brief sketch to display Ringer in his double position as clinician and pharmacologist because, as has happened to other great men before him and as must inevitably happen again, his success in two somewhat different fields militated against his receiving, save from those who had intimate opportunities of estimating his worth, quite that high position in medicine to which his qualities entitled him. Had he not devoted a vast amount of time to the scientific work with which his name will ever be associated he might have attained to that high place in professional medicine which Sir William Jenner and others of his colleagues reached. Had he deserted clinical fields and consolidated his attention upon the work of the physiological laboratory his fame as a chemist would have been wider and his contributions to the advancement of chemistry more frequent. We may quote here a passage from *Nature* which puts the view very clearly which we have tried to express. "The solution of salts introduced by him (Ringer), and universally known by his name, is to-day to be found in every biological laboratory, and its use has led to developments in many fields of research. The work on which its composition is based has often received too little attention. This may be accounted for by the time at which it appeared: Ringer's work was done before the modern views of diffusion and dissociation of salts in solution found their way into biology. And the investigators who approached the study of the biological relations of the salts from the side of the new physico-chemistry appear to have overlooked the work of those who had investigated the subject without the aid of the newer methods. Quite recently, however, some amends have been made in this respect, and it is now recognised that the pioneer in this work had reached in essentials the same position nearly twenty years ago as has now been attained generally."

The factor which played the main part in somewhat preventing Ringer from obtaining the public recognition which he deserved was his unobtrusiveness. He was a very quiet reserved man in private life, taking no part in social affairs whatever, and no one, save those collaborating with him, ever heard from him much about his work, its objects and

developments. He made valuable and not infrequent communications to scientific journals, but, save in this way, he effaced himself as far as possible. In 1869 appeared his well-known "Handbook of Therapeutics," which in many directions, as we said ourselves at the time, revolutionised the sciences of which it treated. This manual ran through 14 editions, and at different times during its successful progress from issue to issue we noted the additions, subtractions, and modifications almost always with approval.

Dr. Sydney Ringer was in good health until two or three years ago, but recently a slight cerebral seizure caused his friends anxiety, taken in connexion with his advanced years. The symptoms, however, were passing off when on Oct. 13th a fresh seizure occurred from which he never rallied.

WILLIAM HALL, M.D. BRUX., F.R.C.S. EDIN., L.R.C.P. EDIN., J.P.

BY the death of Dr. William Hall, which occurred on Oct. 25th, Lancaster has lost a highly respected medical practitioner. Born in 1850, he was educated at the Lancaster Royal Grammar School, afterwards proceeding to Edinburgh, where he obtained the Licentiateship of the Royal College of Surgeons in 1871. In the following year he became a Licentiate of the Royal College of Physicians, and in 1886 obtained the surgical Fellowship and the degree of Doctor of Medicine at the University of Brussels. Upon qualifying he joined his father, with whom he continued in practice in Lancaster till 1883. After the retirement of Dr. Hall senior, the practice was continued jointly with Mr. J. H. Irvin, and was subsequently amalgamated with another practice. Dr. Hall was at one time district surgeon to the London and North-Western Railway and honorary local secretary for the Lancashire and Cheshire branch of the British Medical Association, of which branch he has filled the office of president. For 37 years Dr. Hall was connected with the Royal Lancashire Infirmary. In 1873 he was elected an honorary surgeon, and in 1880 he was appointed a trustee of the institution, subsequently becoming its president, an office which he held for two years. In the erection of the present infirmary he took an active part and was among those presented to the King when, as Duke of York, he opened the building in 1896. He took a great interest in public matters, and besides having filled the office of town councillor was one of the Charity Trustees. For 28 years he was connected with the 5th Royal Lancashire Artillery, from which company he retired with the rank of surgeon-major in 1899.

Dr Hall leaves a widow, the daughter of Colonel Cotton, whom he married in 1874, and five daughters. To the poor Dr. Hall was always a friend, and he will be greatly missed by them as well as by his many friends and the public generally. As a mark of respect the flags on the town-hall, the Royal Infirmary, and other public buildings in Lancaster were flown at half-mast when his death became known.

CHARLES EDWARD ADAMS, M.B., B.SC. LOND., M.R.C.S. ENG.

Dr. C. E. Adams, whose untimely death occurred at Buckhurst Hill after a long and painful illness, was only 49 years of age. He settled in Buckhurst Hill in 1885, the same year in which he qualified. He never spared himself in the interests of his numerous patients. Of a retiring nature, he never busied himself with public affairs, but, keenly imbued as he was with the high responsibilities of his profession, he created a reputation for himself as an able diagnostician and a sound clinician amongst his *confrères* in the district. In recent years he had taken a very leading part in the movement to provide a new and efficient hospital for the neighbourhood. Unhappily, he has not been spared to see the completion of this scheme. Apart from medicine he had educated himself to be an accomplished musician, and, what is unusual in an amateur, his talent lay in composition. For many years he was the conductor of the local musical society, and the president of the choral society. During his 25 years of active life in Buckhurst Hill he endeared himself to all classes and denominations by his sweet gentleness and never-failing courtesy. He was an ideal practitioner, combining the courtliness of the older generation with the keener scientific ideals of the later school.

M. KRÖNLEIN.

THE town of Zürich, and especially the medical faculty of the University, deplore the death of Dr. M. Krönlein, who for 29 years occupied the position of teacher of clinical surgery at the University of Zürich. Born at Schaffhausen in Switzerland in 1846, he studied in Zürich, took his medical degree in 1870, and immediately took charge of three surgical wards in the Franco-Prussian war. For three years he was Professor Rose's surgical assistant, from 1873 to 1881 he acted as first assistant to Professor von Langenbeck in Berlin, taking a similar charge in Zürich in 1881. He was well known in the medical world as the author of no less than 84 publications. We may here mention his contribution on luxations in the Encyclopædia of Billroth and Luecke, and his smaller works on the surgery of the brain and kidneys. He was the first in Switzerland to perform the operation for appendicitis and the first to extirpate with success a sarcoma of the lung. He was very active in university affairs, and, as dean and rector, took the greatest interest in the development of the surgical department. Appreciated alike for his conscientiousness, industry, and the thoroughness of his knowledge, hundreds of young medical men owe much to his teaching, and a goodly number of his assistants have to thank him for their advancement in life.

Dr. Krönlein died after several months of severe suffering from attacks of angina pectoris, succumbing on Oct. 25th; his remains were cremated on the 28th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Joseph Forster, professor of hygiene in the University of Strasburg, who was an LL.D. of the University of Edinburgh, and a member of numerous medical and scientific societies and academies, and editor of the *Archiv für Hygiene*. He was born in 1844, and studied in Leipsic and Munich under Pettenkofer and Voit. His first professorship was that of hygiene at the Munich Veterinary School, but a year later he was appointed to the chair of hygiene in the University of Amsterdam, where he remained until he was invited to Strasburg to undertake the direction of the recently erected Institute of Hygiene and Bacteriology in 1896. He made many important researches on food sanitation and in bacteriology. Amongst other things he showed that a number of microbes not only retain their vitality at 0° C. but multiply and develop at that temperature so as to produce decomposition of tissues; also that the phosphorescent appearances often noticed in the sea are really due to micro-organisms.—Dr. William G. Daggett, lecturer on medicine in Yale.—Dr. G. Baumgarten, professor of medicine in Washington University, St. Louis.—Dr. Herbart, formerly physician to the Dunkirk Hospital.—Dr. Moritz Hofmann, formerly extraordinary professor of forensic medicine in the University of Munich.—Dr. J. V. Shoemaker, professor of materia medica and therapeutics in the Medico-Chirurgical College, Philadelphia.—Dr. Carey Kennedy Fleming, professor of abdominal surgery in the Denver and Gross College of Medicine.—Dr. J. P. Rottot, formerly professor of clinical medicine in the Montreal School of Medicine and Surgery.—Dr. A. Angelby, whose name is known as an enthusiastic worker in the field of the administration and management of French mineral springs.—Dr. Obdulio Hernandez, professor of external pathology in the University of Buenos Aires.—Dr. Rafael Herrera Vegas, a distinguished practitioner in Buenos Aires, who had been an honorary member of the Commission appointed to study and report upon the question of Yellow Fever.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this association will be held at 3 o'clock on Tuesday, Nov. 15th, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. John Macpherson. There will be a meeting of the Educational Committee at 10 A.M., of the Parliamentary Committee at 11.30 A.M., and of the council at 12.30 P.M. In the evening the members will dine together at the Café Monico at 7 o'clock, the price of the dinner being 7*s.* 6*d.*, exclusive of wine. Evening dress will be optional. All communications should be made to Dr. C. Hubert Bond, honorary general secretary, 11, Chandos-street, Cavendish-square, London, W.

Medical News.

THE QUEEN'S UNIVERSITY OF BELFAST.—The following candidates have passed the D.P.H. examination:—

R. G. M. Clements, M.D., Charles Dickson, M.B., G. W. M'Comb, M.B., and *J. A. Sinton, M.B., D.P.H. Cantab.

* Passed with distinction and awarded special prize.

FOREIGN UNIVERSITY INTELLIGENCE.—*Altanta (College of Physicians and Surgeons):* Dr. Harry S. Bachmann of Philadelphia has been appointed Professor of Physiology.—*Berlin:* Dr. Lesser, Extraordinary Professor of Dermatology, has been promoted to an Honorary Professorship. Dr. Fritz Frankenhäuser (*privat-docent* of Medicine), Dr. Ulrich Friedemann (*privat-docent* of Hygiene), and Dr. Egon Thomasczewski (*privat-docent* of Dermatology) have been granted the title of Professor. Also, in connexion with the termination of the tenth of the study journeys, Dr. Oliven, Dr. Bassenge, and Dr. Kaminer have been granted the title of Professor.—*Bologna:* Dr. F. Caldesi has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Budapest:* Dr. Franz Gebhardt and Dr. S. Ritook have been recognised as *privat-docenten* of Medicine, Dr. R. Bálint as *privat-docent* of Neurology, and Dr. E. Scipiades as *privat-docent* of Midwifery and Gynæcology.—*Cincinnati (Ohio-Miami Medical College):* Dr. McElderry Knower, Adjunct Professor in Toronto University, has been appointed Professor of Anatomy in succession to Dr. Lewis.—*Cordova (National University):* Dr. Aquiles Villalba has been appointed to the chair of Bacteriology; Dr. Antonio Nores to that of Operative Medicine; and Dr. Alejandro Centeno to that of Clinical Medicine.—*Cracow:* Dr. Thadée Kozniewski has been recognised as *privat-docent* of Pharmacology.—*Heidelberg:* Dr. Zade of Jena has been recognised as *privat-docent* of Ophthalmology.—*Leipsic:* Dr. Hans Steinert, First Assistant in the University Medical Clinic, has been appointed Extraordinary Professor of Medicine.—*Munich:* Dr. Karl Kopp, *privat-docent* of Dermatology, and Dr. Wilhelm Herzog, *privat-docent* of Surgery, have been promoted to Extraordinary Professorships.—*Palermo:* Dr. Giacinto Viola of Messina has been appointed Professor of Internal Pathology.—*Parma:* Dr. Franco Carini has been recognised as *privat-docent* of External Pathology.—*Pavia:* Dr. Luigi Frigerio of Sienna has been recognised as *privat-docent* of Psychiatry.—*Philadelphia (University of Pennsylvania):* Dr. A. N. Richards, Professor in the Northwestern Medical School, Chicago, has been appointed Professor of Therapeutics and Pharmacology in succession to Dr. Edsall.—*Rome:* Dr. Augusto Giannelli has been recognised as *privat-docent* of Neurology.—*Sienna:* Dr. Teodoro Zoras has been recognised as *privat-docent* of Bacteriology.—*Toronto:* Dr. John A. Amyot has been appointed Professor of Hygiene in succession to Dr. Oldright, resigned.—*Tübingen:* Dr. G. Perthes, Extraordinary Professor in Leipsic, has been appointed to the chair of Surgery in succession to Dr. P. von Bruns, resigned.—*Vienna:* Dr. Vikkov Widakowich has been recognised as *privat-docent* of Embryology.

THE ANTIVIVISECTION HOSPITAL: A CASE IN THE CORONER'S COURT.—On Wednesday, Nov. 1st, a case was investigated at the Battersea coroner's court by Mr. John Troutbeck, who held an inquiry with respect to the death of an infant aged 9 months. Evidence was given to show that on Thursday, Oct. 27th, the child while at the house of an aunt was placed on the floor and seen to put a piece of coal to his mouth, when he "turned blue" almost at once. Concluding that he had swallowed some coal the child's uncle snatched him up and ran off with him to the nearest practitioner's. Here an examination failed to discover the presence of coal, but the medical man advised that the child should be taken to the Bolingbroke Hospital. This advice was not followed because there was no conveyance immediately available, but the baby was taken by a neighbour, who started with the intention of going to St. Thomas's Hospital, to the Antivivisection Hospital (the Battersea General Hospital), the symptoms having grown so alarming that the change of plan seemed necessary. In her evidence the child's aunt said that at the Antivivisection Hospital a nurse told her she must go to the relieving officer and get a paper because they were going to send the child to the infirmary. They had done what they could, the nurse said, and had used the stomach-pump, but could not find any coal. The nurse also said there must be an immediate operation. The coroner asked why the child should be removed, seeing it was already at a hospital. This question the witness confessed her inability to answer. Mr. Cartwright Sharp, who appeared on behalf of the hospital authorities, asked the witness if she was sure the nurse said anything about the stomach-pump. She replied that she was; and her husband said the medical man at the hospital told him the child had been ill two or three days and was suffering from scarlet fever and pneumonia in the right lung, and, moreover, was in a dying condition. "I'm certain of this," the witness said, when questioned by the coroner. He stated further that the doctor at the hospital said: "I can do nothing for the child here. You had better take him away." When the witness said he could not take him away, the doctor said, "Shall I telephone to the infirmary?"—The Coroner: Did the doctor give no reason for removing the child?—Witness: Yes; he said I haven't got a bed. We don't keep beds for children here.—The Coroner: Had you told him the child had swallowed coal?—Witness: I told him I thought he had. Mr. Sharp questioned the witness, who in the main adhered to his statements. The neighbour who had brought the child gave a slightly different version. She said the doctor at the hospital said the child had a rash coming out which might prove to be scarlet fever, and asked, "Will you take him home and have a private doctor or shall we send him to the infirmary, as we have no bed?" Dr. W. L. Maccormac, the assistant medical superintendent of the infirmary, said that he received a telephonic message from the sister at the Antivivisection Hospital. So far as he remembered, the message was that she was speaking on behalf of the resident medical man, as they had a baby at the hospital who required tracheotomy. Asked if it was diphtheria she replied "I don't think the doctor quite knows." Nothing was said about coal. When admitted the child was practically dead. Witness immediately put a tube in the windpipe, operating in the kitchen of the receiving ward. The child revived but afterwards developed pneumonia and died on Saturday night. On making a post-mortem examination he found a piece of coal jammed in the "voice-box." It would have been difficult to locate it, and to remove it would have required a rather heroic operation. The pneumonia was caused by the presence of the coal. Mr. Cartwright Sharp suggested that tracheotomy was an operation which required the administration of chloroform or the presence of a skilled assistant. "I had to do it single-handed," said Dr. Maccormac. The resident medical officer at the Antivivisection Hospital, said he examined the throat thoroughly but could find no foreign body. Although very ill, he did not think the child was *in extremis*. He ordered a hot bath and a mustard poultice, as he thought he discovered a patch of pneumonia. In view of the history of the coal, and having no bed, he thought it best to get the patient into some other public institution. The sister suggested the infirmary. He did not know she said "instant tracheotomy" or "tracheotomy" was necessary. The sister was a little enthusiastic and sometimes she exceeded her instructions. The Coroner observed that on this occasion her enthusiasm seemed to be well directed. "Tracheotomy has been done and the child died," said the witness. The Coroner asked what he meant. He replied that when he saw the child he did not see any indication for tracheotomy, which a juryman observed was "rather a feeble answer."—The Coroner: Why was this child not kept in?—Witness: We had not a bed.—The Coroner: Do you mean to say you could not make shift to put up a bed for a child of 9 months?—Witness: I daresay we might if we had thought of it. I thought the child would be better in an institution where there was a bed.—The Coroner: That's putting the hospital on a lower level than the infirmary.—Witness: I recognised the possible necessity of tracheotomy; that is why I sent it.—The Coroner: Why did you not do the tracheotomy yourself?—Witness: I thought it was not safe to do so without the assistance of someone at that stage.—The Coroner: Could you not have got assistance?—Witness: Not in the same time as in an institution where they have more capacity than we have. The father of the child heatedly asked for a further explanation. He was told by the witness that he thought the child could be best treated in a public institution where there were

more available appliances. He thought it quicker to send to another institution than to telephone for another medical man to assist him. They would probably not have come—they would have come, but they might not have come quickly. It was quite a matter of chance, while it was a certainty that the infirmary would take the case in, and that it would be properly attended to there. The Coroner, addressing the jury, remarked that it was difficult to understand the story of the child's reception and treatment at, and removal from, this general hospital. "I take no notice," he continued, "of the answer given me that the child had tracheotomy performed and it died. It is an unfortunate answer. I think it is better ignored." The jury returned a verdict in accordance with the medical evidence, and added this rider: "The jury do not appreciate the action of the Antivivisection Hospital authorities."

HUNTERIAN SOCIETY.—This society awards a silver medal annually for the best essay by a general practitioner embodying the results of his own observations. Intending candidates are reminded that the last day for sending in essays for the present competition is Dec. 31st, 1910. Any further particulars may be obtained from the honorary secretaries, 60, Welbeck-street, London, W.

SOUTH LONDON INSTITUTE FOR THE BLIND.—Lord Southwark, the president and chairman of the South London Institute for the Blind, has sent us an appeal on behalf of this institution, which is doing good work by educating and providing work for the blind and by supplying a home for young unmarried blind women. A sum of £2000 is required to meet existing liabilities. Contributions may be sent to the Rev. St. Clare Hill, 83, Borough-road, London, S.E. The bankers are the London and South-Western Bank, St. George's Circus, London, S.E.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—A meeting of this society was held on Oct. 21st. The accounts presented showed that the business of the society during the summer months had been as usual very satisfactory. The list of members permanently incapacitated continues to grow, but the ordinary sickness claims are fewer in number and of less duration than was expected, and, on the whole, there is a good margin in favour of the society. At each valuation of the society's business a special reserve is made in respect of the chronic sickness cases. Prospectuses and all further particulars may be obtained on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A council meeting of the association was held at the Holborn Restaurant on Oct. 19th, Dr. F. G. Crookshank being in the chair. The treasurer, Mr. E. G. Gibbs-Smith, reported a balance in hand. In accordance with the decision of the general meeting held in London, the terms of a letter to be sent to a number of societies and associations which represent the various interests of practitioners who hold public appointments under local and central authorities were discussed, and it was decided to ask for a preliminary meeting in which the interested societies could discuss the methods by which a mutual coöperation could be rendered possible. All communications should be made to Mr. D. A. Belilios, honorary secretary, at 109, Queen's-road, Wimbledon.

THE MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND, LIMITED.—The eighth annual general meeting of this union was held at Glasgow on Oct. 13th. Sir Hector C. Cameron occupied the chair, and there was a large attendance of members. The chairman, in submitting the annual report of the council, referred to the prosperous condition in which the finances of the union now stood. He stated that over one-fifth of the invested funds were derived from the excess of income over expenditure during the past year and that the fund now stood at £1849, which was equivalent to £1 10*s.* 2*d.* per member. He also referred to the insurance scheme under which, for a small premium, members are indemnified against claims of damages in the event of an action being unsuccessfully defended. In view of the fact that claims against members of the medical and dental professions are on the increase, the chairman emphasised the advice given by the council that every member of the professions in Scotland should not only be a member of the union but should be protected by an indemnity policy. The report was unanimously agreed to, and thereafter the election of office-bearers took place.

ARMY MEDICAL SERVICE.—An examination of candidates for not less than 15 commissions in the Royal Army Medical Corps will be held on Jan. 25th, 1911, and following days. The presence of candidates will be required in London from Jan. 23rd.

THE LONDON HOSPITAL MEDICAL COLLEGE.—We are desired to state that all members of the profession are cordially invited to the two lectures to be delivered by Mr. Hurry Fenwick in the clinical theatre of this hospital at 1 P.M. on Tuesdays, Nov. 8th and 15th.

THE M'CUNN SCHOLARSHIP.—Dr. A. Philp Mitchell, resident surgical officer at the Chalmers Hospital, Edinburgh, has been awarded the M'Cunn Scholarship in Surgery (value £100) open to all graduates of medicine of the Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews of not more than three years' standing.

THE ILLUMINATING ENGINEERING SOCIETY.—A meeting will be held at the house of the Royal Society of Arts (John-street, Adelphi, London) on Nov. 8th, at 8 P.M., when a paper on Recent Advances in, and the Present Status of Gas Lighting, will be read by Mr. F. W. Goodenough. The chair will be taken by the President, Professor S. P. Thompson, D.Sc., F.R.S.

THE TYNDALL SCHOLARSHIP.—This scholarship, which was founded by Mrs. Tyndall, widow of the celebrated scientist, for research in connexion with the welfare of miners, has been awarded by the Royal Society to Mr. T. L. Llewellyn, M.D. Lond. The subject of Dr. Llewellyn's research work for which the award has been made is Nystagmus.

GLASGOW UNIVERSITY CLUB, LONDON.—The members of this club will dine at the Gaiety Restaurant, Strand, W.C., on Nov. 25th, at 7.30 P.M. The Right Hon. Lord Curzon of Kedleston, Lord Rector of the University, will occupy the chair. Members who intend to be present, or to introduce guests, are requested to give notice as early as possible to the honorary secretaries, 4, Bryanston-street, Portman-square, W.

ROYAL INSTITUTE OF PUBLIC HEALTH.—Two lectures will be given by Dr. C. Levaditi of the Pasteur Institute, Paris, on Monday and Tuesday next, the 7th and 8th instants, at 5 P.M., in the lecture room of the institute. The first lecture will deal with Phagocytosis and its Importance in Immunity; the second with Recent Epidemiological and Experimental Researches on Infantile Paralysis.

LITERARY INTELLIGENCE.—A new edition of "A Text-book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease," by Arthur R. Cushny, M.D. Aberd., F.R.S., is announced for publication by Messrs. J. and A. Churchill.—Mr. H. K. Lewis announces for early publication an entirely new work on "Medical Diagnosis" by Dr. W. Mitchell Stevens of Cardiff. Mr. Lewis also announces the immediate issue of a new booklet by Dr. Mildred Burgess on "The Care of Infants and Young Children in Health."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CHARLES, H., M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Middlesex Hospital.

COOMBES, P. C., M.R.C.S., L.R.C.P. Lond., has been appointed Senior Assistant Medical Officer of the Surrey County Asylum, Brookwood.

EMSLIE, BELL, M.B., Ch.B., has been appointed Third Assistant Medical Officer at the Stirling District Asylum, Larbert.

GREEN, T. A., M.D., F.R.C.S. Edin., has been appointed School Medical Officer to the Bristol Education Authority.

HAWKSLEY, W. L., M.B., Ch.B., D.P.H. Liverp., has been appointed Assistant to the Medical Officer of Health for the City of Liverpool.

HEATH, H. LLEWELLYN, L.S.A., D.P.H. Cantab., has been appointed Temporary County Medical Officer to the Public Health Committee of the East Suffolk County Council in connexion with the Prevention of Plague.

LEGG, T. P., M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to King's College Hospital.

MACASKILL, D. C., M.B., Ch.B. Edin., has been appointed Second Assistant Medical Officer at the Stirling District Asylum, Larbert.

MILNE, R., F.R.C.S. Eng., has been appointed Extra Assistant Surgeon to the London Hospital.

REES, W. T., M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Llanwrtyd Wells and Llandulas portion of Builth Union.

SUTHERLAND, H. G., M.D., Ch.B. Edin., has been appointed Medical Officer to the St. Marylebone Anti-Tuberculosis Dispensary.

SWAN, R. H. J., F.R.C.S. Eng., M.B., M.S. Lond., has been appointed Surgeon to the Cancer Hospital.

WALTON, A. J., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Dreadnought Hospital, Greenwich.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARMY MEDICAL SERVICE.—Fifteen Commissions in the Royal Army Medical Corps.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—Honorary Ophthalmic and Aural Surgeon. Also House Surgeon. Salary £100, with board, residence, and laundry.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £200 per annum, with rooms, fire, light, and attendance.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Junior House Surgeon. Salary £80 per annum with board, residence, washing, &c.

BOOTLE, COUNTY BOROUGH OF.—School Medical Officer. Salary £250 per annum.

BOURNEMOUTH, ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.—Honorary Medical Officer.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with apartments, board, and laundry.

BRISTOL ROYAL INFIRMARY.—Honorary Dental Anæsthetist.

CANCER HOSPITAL, Fulham-road.—Surgeon.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with board, lodging, and washing.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £80 per annum, with board, apartments, and laundry.

CRICHTON ROYAL INSTITUTION.—Two Crichton Fellowships in Pathology and Bacteriology. Salary £250 per annum each, with board, quarters, attendance, and laundry.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, &c.

EASTERN DISPENSARY, Leman-street, E.—Resident Medical Officer. Salary £120 per annum, with residence and attendance.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

FOLKESTONE, ROYAL VICTORIA HOSPITAL.—Resident House Surgeon. Salary £100 per annum, with apartments, board, and laundry.
FRENCH HOSPITAL, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer, unmarried. Salary £50 per annum, with board and laundry.
GLASGOW, UNIVERSITY OF.—Examiner in Physiology, Examiner in Surgery (Systematic and Clinical), and an Examiner in Medicine (Systematic and Clinical).
GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.
HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, board, and washing.
INFANTS HOSPITAL, Vincent-square, Westminster.—Physicians' Assistant. Salary £80 per annum.
ITALIAN HOSPITAL, Queen-square, W.C.—House Surgeon for six months. Salary £60 per annum, with board and residence.
KING'S COLLEGE HOSPITAL, London, W.C.—Senior Surgical Registrar and Tutor.
LEICESTER INFIRMARY. – Assistant House Surgeon. Salary at rate of £60 per annum, with board, apartments, and washing.
LIVERPOOL, CITY EDUCATION COMMITTEE.—School Medical Officer. Salary £250 per annum.
LIVERPOOL INFIRMARY FOR CHILDREN, CLINICAL SCHOOL.—Resident House Physician. Salary at rate of £60 a year, with board and lodging.
LONDON HOSPITAL, E.—Medical Officer in charge of Department of Electrical and Physical Treatment.
MAIDSTONE, KENT COUNTY OPHTHALMIC HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.
MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80 per annum, with board, residence, and washing.
MANCHESTER ROYAL INFIRMARY CONVALESCENT HOSPITAL, Cheadle.—Assistant Medical Officer, unmarried, for six months. Salary at rate of £80 per annum, with board and residence.
MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician. Salary £75 per annum, with board, residence, and washing. Also Honorary Dental Surgeon.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Second Junior Obstetric Assistant (female) for Maternity Department for three or six months.
ROYAL HOSPITAL OF BETHLEM, Lambeth-road, S.E.—Resident Physician and Medical Superintendent. Salary £750 per annum.
ST. PANCRAS INFIRMARY AND WORKHOUSE.—Assistant Medical Superintendent and Assistant Medical Officer. Salary at rate of £135 per annum.
STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.
STOBHILL GENERAL HOSPITAL, Springburn.—Resident Senior Assistant Medical Officer. Salary £150 per annum, with board and apartments.
STROUD GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.
SURREY COUNTY LUNATIC ASYLUM, Netherne, Merstham.—Second Assistant Medical Officer, unmarried. Salary £200 per annum, with board, lodging, and laundry.
TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.
WIGAN, COUNTY BOROUGH OF.—Medical Officer of Health. Salary £500 per annum.
WREXHAM INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

MARRIAGES.

BRYAN—SMYRK.—On Oct. 27th, at the Parish Church, Henley-on-Thames, Frederick Bryan, M.B., to Ellen Smyrk, youngest daughter of the late Frederick Smyrk, of Waltham Cross.
TOVEY—PRIESTLEY.—On Sept. 10th, at St. Peter's, Wellington, New Zealand, Arthur Hamilton Tovey, M.R.C.S. Eng., L.R.C.P. Lond., to Florence, daughter of the late William Hudson Priestley, of Liverpool.

DEATHS.

BUCK.—On Oct. 27th, at Springfield, Upper Clapton, N.E., Henry John Buck, L.R.C.P. Edin., aged 74 years.
HALL.—On Oct. 25th, after a brief illness, at Elmsfield, Lancaster, William Hall, M.D., F.R.C.S., J.P., aged 60 years.
PENNY.—On Oct. 24th, at Worthing, Charles Burnage Penny, M.B., M.R.C.S., L.R.C.P. Lond., aged 34 years.
WELCH.—On Oct. 25th, at Carrsleigh Cottage, Southborough, Surgeon-Colonel Francis H. Welch, F.R.C.S., Medical Staff (retired), aged 71 years.
WRIGHT.—On Oct. 25th, at Castle-place, Nottingham, Thomas Wright, M.D., M.R.C.S. Eng., aged 88 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A QUESTION OF FEES.

"A Canadian Physician" writes to us on this subject in reference to the letter signed "M.B., F.R.C.S.," in our issue of Oct. 15th. He contrasts the gratuitous treatment which he himself received at the hands of an American consultant physician with the payment of fees to an English aural surgeon whose services he had sought for his child. It is quite clear that general rules of professional conduct cannot be founded on one or two special incidents, and, as a matter of fact, "A Canadian Physician's" experiences are contradicted by other communications which we have received on the same subject. Most English practitioners, general or consultant, in all ordinary circumstances give advice to brother practitioners gratuitously, devotedly, and without stint. All operating surgeons, especially those who acquire a great reputation in some particular line, and all specialists cannot in all circumstances attend all the children of all the medical men of all the nationalities in the world gratuitously. It follows that to a certain extent every case must be judged on its own merits.

THE PROGRESS OF INTELLIGENCE.

To the Editor of THE LANCET.

SIR,—The clear conclusion anyone must draw on reading the extensive and costly advertisements of irregular practitioners and quack medicine vendors is that intelligence among the educated classes is at a very low ebb. For the dupes and credulous believers, who indirectly pay the enormous cost of these advertisements, are not the poor and uneducated, but the well-to-do and educated. I have at the present time under my care a clergyman, two University men, and a well-to-do City man, all of whom have been duped. One, with atheromatous arteries and high blood pressure, underwent a course of physical culture cure at an enormous expense! I cannot get from them any answer to this simple question, Why do you believe these poorly educated persons know more about disease than professional men whose education is special to the subject?

I am, Sir, yours faithfully,
New Cavendish-street, W., Oct. 29th, 1910. THOMAS DUTTON.

AN IMPROVED RAILWAY MILK-CHURN.

Mr. Harold Wickham, of "Caldbec," Station-road East, New Oxted, has submitted to us for inspection a model of his improved railway milk-churn, the chief merit of which is its dirt- and dust-excluding properties. The lid is deep and is removed entirely from the body of the churn in the same way that a lid is taken off a tin canister. There is a bayonet joint fastening it down, and a padlock is provided to prevent any tampering with the milk on its journey. The arrangement obviously provides against the contamination of milk which it sustains too easily during its transit either by rail or cart in the ordinary churn. The top of the ordinary milk churn is often a veritable trap for dirt, which finds its way into the milk. In Mr. Wickham's churn provision for ventilation is made and the churn appears to us to be as easily handled and moved as the ordinary railway churn.

DOUBTFUL PROGRESS.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a pretentious volume, profusely illustrated, entitled "..... in the XX. Century, Contemporary Biographies," the name omitted being that of a southern county. I trust that this work is the first and may remain the last of the kind, for it contains names of 150 medical men, nearly all accompanied with portraits and notices, generally much in excess of that allowed in the Medical Directory, some indeed running to between 30 and 40 lines of self-commendation and genealogy. The volume ends appropriately with similar notices and portraits of veterinary surgeons and breeders of sheep.

It has been said that progress is to be sought in the north, but truly in the south our profession would seem to be moving on. Whither?

I am, Sir, yours faithfully,
Oct. 31st, 1910. SLOW COACH.

MARTIN'S INHALER.

THIS inhaler, which was sent to us for an opinion by Mr. H. H. Sharland, optician, of 7 and 8, Thavies Inn, Holborn-circus, E.C., is of the ordinary wash-bottle type. It consists of a square bottle made of blue glass, provided with a cork through which two tubes are fitted, one (the shorter tube) serving as a mouthpiece, and the other a tube which dips into the medicament. The mouthpiece tube is provided with a valve which allows of the passage of the medicated air only in one direction, so that at no time can there be pressure in the bottle which would discharge the fluid through the dip-tube. We can see no special novelty about the inhaler; it is certainly simple, but doubt may be expressed as to whether it is as effective as other forms.

WANTED, A SUGGESTION FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—Can any of your readers offer me any suggestions as to the treatment of my case? I am 70 years of age and in good health, no gouty or rheumatic history, no deposits or contractions of the tendons, abstainer, and eat moderately of animal food. For the last three months I have had some rheumatic arthritis in my knee-joints, with slight effusion. If I go out for a day's shooting I am stiff in my knee-joints for several days and there is always some tenderness and stiffness remaining. I have tried pot. iod., sod. sal., guiacol carb., and the Tallerman heat; the latter does me good, but I do not like to think that this common condition has "come to stay," and should be thankful for any help. I am, Sir, yours faithfully,

Nov. 1st, 1910. M.D.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Nov. 4th–12th (London).—Ninth International Motor Exhibition.
,, 7th–12th (Cape Town).—Twelfth South African Medical Congress (1910).
,, 11th–19th (London).—Stanley Exhibition.

In 1911:—

May–October (Dresden).—International Hygiene Exhibition.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
Sept. 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 24th–30th (Rome).—International Congress on Tuberculosis.
,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.

In 1912:—

September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
September (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—

(London).—Seventeenth International Congress of Medicine.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Jonathan Hutchinson, L. A. Dunn): at 5.30 P.M.

Debate:

On the Treatment of Fractures in the Neighbourhood of Joints (opened by Mr. Robert Jones (Liverpool) and continued by Mr. Warren, Mr. Lett, Mr. Whitelocke, Mr. H. J. Paterson, and others).

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Albert Carless, James Galloway): at 8 P.M.

Cases:

Dr. A. H. Miller: (1) Adiposis Diffusa; (2) Multiple Lipomatosis.
Dr. Eric Pritchard: Adiposis Diffusa.
Dr. E. Farquhar Buzzard: Tabes with Lumbo-sacral Arthropathy.
Dr. Arthur Latham: Infective Endocarditis, Blood becoming Sterile after Fifteen Months' Vaccine Therapy.
Dr. James Galloway: Painful Necrosis of Extremities.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Mr. E. H. Farr and Mr. R. Wright: A Critical Note on Several Processes for the Determination of the Alkaloids in Colchicum Seeds.—Mr. H. Finnemore: Chemical Examination of a Series of Prunus.—Prof. H. D. Greenish and Miss D. Braithwaite: The Drug Room Beetle (Sitodrepa Panicla) (illustrated by lantern slides).

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5.30 P.M., Major C. E. Pollock, R.A.M.C.: Malingering.—Major S. L Cummins, R.A.M.C.: Guinea-worm in Egypt.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Clinical Meeting.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, Russell-square, W.C.

FRIDAY.—5 P.M., Mr. W. A. Gant (Cambridge): The Foundation of School Dentistry.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY—5 P.M., Sir T. C. Allbutt, K.C.B.: Greek Medicine in Rome. (Fitz Patrick Lecture.)
THURSDAY.—5 P.M., Dr. W. Bulloch: The Problem of Pulmonary Tuberculosis considered from the Standpoint of Infection. (Horace Dobell Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Injuries and Diseases of Arteries. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. D. Ferrier: Traumatic Neuroses.
TUESDAY.—4 P.M., Dr. P. Parkinson: Clinique (Medical). 5.15 P.M., Lecture:—Mr. F. C. Wallis: Cancer of the Rectum.
WEDNESDAY.—4 P.M, Mr. J. Cantlie: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. F. C. Wallis: Cancer of the Rectum.
THURSDAY.—4 P.M., Dr. W. Carr: Clinique (Medical). 5.15 P.M., Lecture:—Mr. F. C. Wallis: Cancer of the Rectum.
FRIDAY.—4 P.M., Mr. E. Clarke: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. R. Lloyd: Anæsthetics.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Pritchard: Medicine.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. C. Hughes: Anæsthetics.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Ulceration of the Cornea.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 30 P.M., Special Lecture:—Dr. C. O. Hawthorne: Infantile Scurvy.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. H. Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient: (Dr. A. J. Whiting). 4.30 P.M., Lecture: Mr. Carson: Acute Abdominal Conditions.
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Dr. A. E. Giles: Vicarious Menstruation.
FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

MONDAY.—5 P.M., General Meeting.

LONDON HOSPITAL MEDICAL COLLEGE, Clinical Theatre, London Hospital, Mile End-road, E.

TUESDAY.—1 P.M., Clinical Surgery Lecture:—Mr. E. H. Fenwick: The Diagnostic Aspect of the Pain in Kidney Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. H. Howell: Specimens illustrating the Pathology of Paraplegia.

FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. P. Sargent: Cervical Ribs.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. Atkinson: Nose.

FRIDAY.—3.45 P.M., Dr. D. McKenzie: Labyrinth.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Inman: Laboratory Diagnostic Methods.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Syphilis (continued): Papular (I., Miliary; II., Lenticular; III., Squamous; IV., Moist). Pustular and Tuberculous.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. Bythell and Dr. C. Moore: The X Ray Examination of the Stomach by means of Bismuth Meals. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (9th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (10th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (12th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Fitz Patrick Lectures

ON

GREEK MEDICINE IN ROME.

Delivered at the Royal College of Physicians of London

BY SIR T. CLIFFORD ALLBUTT, K.C.B., M.D. CANTAB., F.R.S.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

LECTURE II. *

PRESIDENT AND FELLOWS,—My last lecture ended with an allusion to the poison lore of the ancients, a literature in itself; with an allusion therefore I had to be content for time presses, and we must turn to other and less sinister subjects. And none in this period is of greater historical interest than the pulse doctrines.

Pulse doctrine.—Broadbent, in the introductory chapter of his treatise on the pulse, set forth the Galenic doctrines sufficiently for his own purpose; but on this occasion we may fitly endeavour to trace more fully and particularly the researches on the circulation of the blood from more ancient times, from Praxagoras of Cos, in the succession of Diocles, through Athenaeus down to Galen, to whom we are chiefly indebted for what we know of the subject. That to feel the pulse was a common practice we note incidentally in such comparatively early passages as:

> "Tange, miser, venas,
> ..... nil calet hic."
> (PERS. Sat. IV.)

and "*Et peragit soliti vena tenoris iter*" (Ovid in Letter X. to Flaccus, speaking of cold and languor without fever). Galen wrote many essays on the pulse, and from his fourth, fifth, eighth, ninth, and nineteenth books, in which he gives a summary and a criticism of the various pulse doctrines from Herophilus to Archigenes, especially in the Περὶ τῶν σφυγμῶν and the Περὶ διαφορᾶς τῶν σφυγμῶν (IVth Book); and from some other sources, as in a certain pseudo-Galenic pneumatist treatise, from a pseudo-Soranic tract published by Rose (Anecdota Gr. II.), and especially from the treatise on the pulse usually attributed to Rufus of Ephesus, a fairly definite reconstruction of the pulse-lore of the ancients has been attained. Galen's main source was a lost treatise—Περὶ σφυγμῶν—of Archigenes,[47] some fragments of which he quotes; though the first treatise on the pulse (Περὶ παλμῶν) was written by Aegimius of Elis, of the period of Hippocrates. But I may take Praxagoras as the first physician to give the pulse its due place in diagnosis and therapeutics. Unluckily Praxagoras taught that the arteries were air channels only, a dogma which provoked grievous dissensions, errors, and abuses through later ages. It would seem that Chrysippus also had emphasised the value of the pulse as a criterion of fever.

In the next place we come to Erasistratus, who described the valves of the heart, the chordæ tendineæ, and the several regions of the arteries and veins in heart and liver more accurately than Herophilus, whose attention was directed rather to the anatomy of the brain. Erasistratus showed by experiments that the arteries contained blood, and he recognised the function of the heart as the prime mover of the circulation. This great master got very near the truth of the circulation, to a point of view too soon to be perverted by pneumatist and other notions, for which he himself was not altogether without responsibility, or, indeed, to be lost sight of in that empirical indifference to anatomy to which I have referred. This insight of Erasistratus (c. 340–324 B.C.) is of much historical importance; for, as we have seen in respect of Praxagoras, before his time the arteries during life were supposed to contain air only—thin air, breath, vapour, spirit, pneuma. It is well, therefore, to quote the very words attributed by Galen (V. 552) to Erasistratus, which are as follows: ἅμα μὲν ἀρχὴν καὶ ἀρτηριῶν καὶ φλεβῶν εἶναι τὴν καρδιάν, ἅμα δὲ τοὺς ἔξωθεν ἔσω νεύοντας ὑμένας ἐπὶ τοὺς εἰσάγουσι τὰς ὕλας ἀγγείας ἐπιπεφυκέναι, φάσκοντος. This Galen repudiated, for how, said he, could the veins originate in the heart when the blood for them is made in the liver? The remarkable hypothesis by which Erasistratus endeavoured to reconcile the new and the old notions of the arterial contents was, that at certain undefined places in the circulatory tree there were communications—anastomoses—between the veins and the arteries; channels which under ordinary circumstances he seems to have assumed to be closed or but sparingly permeable, but in case of lesion or disease opened, so that the blood streamed into the arteries (παρέμπτωσις) and became one of the causes of fever. To this hypothesis in respect to hæmorrhage we shall return, for certain therapeutical means were founded upon it.

Yet strangely enough, both as regards the physiology of the circulation, and in medicine, the Erasistrateans paid less attention to the pulse than did the Herophileans, perhaps because of their reluctance to bleed. In their clinical appreciations Herophilus and his immediate disciples seem to have been properly content with four excellent indications of the pulse—namely, size, strength, rate, and rhythm; but the later disciples of his school too sedulously and fancifully overargued its signs, splitting them into a multitude of unreal categories. Archigenes, of whose elaborate treatise, under the title of Περὶ σφυγμῶν, Rufus gives some account, and of which some excerpts have survived, in his recognition of eight categories only "as generally known," was economical. However, his modest eight, it would seem, we must make into ten; for on turning to Daremberg's Rufus we find that "hard and soft," as qualities of "systasis and dialysis," are to be distinguished from "strong and weak," as qualities of tone. These eight, or ten, categories (λόγοι) Galen appears, from his two works on the pulse and a certain pseudo-Galenic chapter, to have adopted (Wellmann). These and other minutiæ, such as pulses hot or cold, dry or moist, &c., if in themselves idle or absurd, are nevertheless serviceable as clews to traditions and authenticities.

When from such records as remain we endeavour to reconstruct the pulse and respiration doctrine of the Pneumatists in the time of Athenaeus—say in the reign of Claudius—they seem to have been after this form. The pneuma, divine energy, or world-soul, permeated the body as πνεῦμα ζωτικόν: but, as Erasistratus taught, it reached the heart by respiration through the lungs as πνεῦμα ζωτικὸν and πνεῦμα ψυχικόν; whence the πνεῦμα ζωτικὸν "sped like a bird" through the arteries and the body, while the πνεῦμα ψυχικὸν was delivered to the brain (Chrysippus). Now as the pneuma reached the heart it met with the blood, both in the arteries, which had their roots in the heart, and in the ventricles; but in the ventricles crasser blood was in excess, in the arteries pneuma. "The arterial blood was thinner, purer, and redder." It seems at this time to have been generally held, in spite of Erasistratus, that the veins had their roots in the liver.[48] The movements of the circulation, systole and diastole, were kept up by the innate heat, identified by the pneumatists with the pneuma, as a single entity; and the harmonious rhythm of these motions was a sign of health. Thus the Praxagorean notion, that the arteries contained pneuma only, appears for the time to have been definitely set aside; though in comparing these records we are often perplexed by equivocal terms. Aristotle seems to have been unaware of the distinctions of Praxagoras between arteries and veins, except in respect of the aorta and venæ cavæ; and he supposed the heart to consist of but three chambers. Especially in this respect we are perplexed in Aristotle, and elsewhere, by the uncertain meaning of the word φλέβς, or *vena*, although Herophilus and Erasistratus clearly distinguished arteries from veins, and the left from the right heart. Celsus, whose testimony in respect of Alexandria is very important, uses *vena* to signify blood-vessels (including arteries); yet he uses the word "*arteriae*" also, on the whole with a definite meaning, and anatomically in our sense—as, for example, "itemque arteriae quas καρώτιδες vocant" (IV. 2); though we observe that with them he classes that main pneumatic channel the *aspera arteria*, or windpipe. And here I may conveniently anticipate matters so far as to say that Galen must have accepted the truth that the arteries contained a

* Lecture I. was published in THE LANCET of Nov. 5th, 1910, p. 1325.

[47] For these paragraphs I am again indebted to Wellmann in his *Pneumatists* and in Susemihl; to Daremberg's *Rufus*; to Celsus himself; to the relics of Archigenes, &c.; and to various commentators on Aristotle and the later sources.

[48] It is worth notice that the Chinese to this day, I am told, think that the right pulse tells the state of the liver, the left the state of the heart.

redder and more ethereal blood[49]; for, as we all know, he assumed the existence of pores in the ventricular septum. He was also aware that the heart was the centre and source of the pulsations, and showed experimentally that if an artery were ligatured—the femoral, for instance—pulsation continued between the ligature and the heart, but ceased beyond it; an observation however which, if taken alone, would not have satisfied those pneumatists who attributed pulsation to the throbbing of the pneuma only, an idea which may now occupy our closer attention. With Galen the difficulty was to understand how Nature, "which does nothing in vain," came to make two different kinds of vessel for the carriage of the blood.

It seems to me then rather difficult in the obscurity of the traditions to discriminate between the great Alexandrians as concerns their anatomical and physiological views respectively, or, indeed, to compare them with precision, though it is clear that in the clinical observation of the pulse the Herophileans were distinctly in advance; but it is probable that not Herophilus only, but also the contemporary Alexandrian School generally, attributed the energy of the arterial pulsation to the heart as the chief seat of the animal pneuma, or innate heat. Moreover, herein they certainly established the important conception of the heart and blood-vessels as an integer, or functional unity; a conception in later times too often forgotten. The pulsation itself they divided into four periods—a contraction, an expansion, and two pauses. Whether both these motions, or only one of them, used energy seems to have been a point of some disagreement; though, as the distinction between cardiac and arterial systole is often obscure, and is not always made quite clear even by Wellmann, it is not quite easy to be sure of the grounds of this dissent. However, to start with, we ascertain from a passage in the 8th volume of Galen (755) that, although in the Herophilean opinion (Susemihl) the systole only used energy, the diastole being mere recoil, according to the later (Roman) school of Athenaeus energy was expended both in systole and in the diastole. The passage being an important one I quote it in the original: "*οἱ δ' ἀπ Αθηνάιου πάντες, ὥς εἴρηται, τὰς κινήσεις ἀμφοτέρας ἐνεργείας ἡγοῦνται, τήν τε ἐν τῷ διαστέλλεσθαι γινομένην καὶ τὴν ἐν τῷ συντέλλεσθαι.*"

Now in some sentences it appears to me that, contrary to our customary use, by systole was intended the lift of the artery, whereas in others, as where it is disputed whether the systole of the pulse can be felt or not, clearly the arterial fall was intended. Moreover, it has been pointed out, I think already on a suggestion of the late Professor Magnus, that many of these writers, at any rate, supposed the heart and the arteries to swell and collapse together; this I had myself observed and illustrated by the following passage: "*δι' ὀγκωσις καὶ συνίζησις αἰσθητὴ καρδιάς καὶ τῶν ὁμοιοπαθούντων αὐτῇ.*" Dicroty, as we gather from Galen, was regarded as a second weaker beat; an explanation which he accepts, comparing it to the second tap of the hammer on the anvil, the anvil being the *σκληρότης* (inertia) of the arterial wall (*σῶμα*).

The Roman pneumatists, even of the ability of Archigenes, hampered as in part they were by the Methodist abstractions of *strictum* and *laxum*, lost sight of some invaluable clinical inferences from qualities of the pulse, which had been perceived by the Alexandrians, and which Galen restored. For instance, these later pneumatists—as we find in Athenaeus, Agathinus, Herodotus, and Archigenes—got entangled in arguments between blood content and pneuma content; and between tone (*τόνος*) as pneuma, and tone as a quality of the arterial wall (*κατὰ τὸ σῶμα τῆς ἀρτηρίας*). In such fragments of Archigenes as we possess (Wellmann) we find this confusion between blood content, pneuma content, and arterial wall. And I may note here, a little before due time, that, so far as I know, Galen was the first to point out that the arterial wall is liable to sclerotic degeneration. So, if we try to get behind these confusions, we shall apprehend that the Alexandrians, nurtured in a more scientific school, had in respect of the circulation perceived certain most important truths afterwards obscured, and that to these forerunners Galen owed not a little, how much we cannot now tell. I may add further this notable instance, that in respect of plethora the difference was then discerned between a long (or sustained) and a short beat, as definitely contrasted with degrees of frequency of beat; and again between the "broad" (*πλατὺς*) pulse—as of a relaxed artery with large output, and an ill-filled pulse. The high pulse (*celer*) of the former case was also described by them; so that they regarded the big pulse (*μέγας*) in three dimensions.

In systole the pneumatists considered that air (pneuma) was drawn in, and in diastole the fuliginous excrement expelled; thus they forwarded the scientific conception of diseases as perversions of the normal. It was especially true of Erasistratus that he fully grasped this idea, only too soon to be vitiated, that disease is a perversion of health, of the normal processes; not a condition contrary or foreign to biological nature. To take a very interesting example: to those of my hearers who are conversant with music the name of Aristoxenus of Tarentum, a pupil of Aristotle, is not unfamiliar, as of one who conceived, or on behalf of his musical tutor recorded, a masterly contribution to the theory of music. Now Aristoxenus flourished in the fourth century just before Herophilus; and it is interesting to find that in his description of the rhythm and arrhythms of the heart Herophilus used the terms of Aristoxenus. For example, in illustration of the idea of morbid as but deviations from normal processes, Herophilus distinguished certain cardiac rhythms as characteristic of periods of life. The rhythm of infancy, he said, was a pyrrhic (∪∪); of adolescence a trochee (-∪); of middle life a spondee (--); of age an iambus (∪-). I am not now concerned to justify these descriptions precisely, but to present them as patterns of method, and of a sound kind of pathology. After him Archigenes likewise described and compared taxic and ataxic pulses—gallop rhythms, palpitations ("spasms") of the pulse and the like—as various degrees of deflexion from the normal into the abnormal. This fruitful conception of the nature of disease unfortunately became distorted by demonology with its magical cures; and also by the kindred if more spectral hunt of the metaphysicians after "morbid entities," a cry which finds an echo in the words of some eminent physicians even of to-day.

After the pulse lore of these schools, I would make some reference to their doctrines on *sexual generation;* for herein also we revere the memory of our immortal Harvey. And when, in comparing his results in this field with those on the physiology of the circulation, we dare to reflect that, as in the times of which we are speaking, even supreme genius cannot penetrate far beyond the limits of contemporary knowledge and means of research, we cast no shadow on that great memory. The problem of generation, as it presented itself to the ancients, is too difficult to put succinctly without a renunciation of much of its detail and of the history of many tides of opinion. Moreover, to make the argument comprehensible, I cannot quite confine myself to the pneumatists; I must make some more general reflections upon its phases from Hippocrates through Aristotle to Galen, that I may indicate the stage where the pneumatists came in. Our sources in this respect are, however, very scanty, and turn chiefly upon what is recorded in Galen's Περ. *σπέρματος* (IV., 593).

Concerning the respective virtues of male and female in the generation and development of the embryo, the opinion of Hippocrates is clear—that the ovaries corresponded to the testes, and that male and female both contributed seed. The superb anatomy of Vesalius left this physiological notion of the matter unaltered, until the seventeenth century when it was undermined by the labour of Highmore, Stensen, and de Graaf. After Hippocrates we come to the opinions of Aristotle, which are too well known to need a careful description here. Suffice it to say that this great sage firmly and consistently denied that the female contributed seed; the semen, the finest concoction of the male blood, as a dynamic element (*τὸ ἄρρεν ποιητικὸν*) quickened the passive but plastic female element (*τὸ θῆλυ παθητικὸν*),[50] enduing it with "form." He saw no difficulty in the resemblance to the mother; for did not plants vary with the soils in which they might be

[49] We know that Galen wrote an essay entitled Εἰ *κατὰ φύσιν ἐν ἀρτηριάις αἷμα περιεχέται.*

[50] It is usually supposed that Aristotle took the *σπέρμα* to imply the body of the fœtus; he seems to have given too much content to the *σπέρμα*, but "form" is far from signifying structure. As we gather from the Eumenides, concerning the appeal for the acquittal of Orestes, the idea of deposit of the embryo by the male to be nourished by the female, as in a nest, was far older than Aristotle, and contains far more than "form." But we must remember that in early times the differentiation of notions to which we are accustomed had not been accomplished.

planted? He admitted that in the catamenia the female contributed some kind of generative substance (γόνη), but contrasting it with σπέρμα, held that it was but of a rudimentary kind. His objection against the seminal contribution of the female, that she could be impregnated without orgasm, and even unconsciously, was less adequate; and how often are we tempted to think how happily we could have jogged the elbow of a great scientific father and supplied him with just the notion he needed. For Aristotle had a good knowledge of the egg, and how well the ovum would have fulfilled his argument;[51] as Fabricius and Harvey perceived, and von Baer finally proved. Straton, so far as we can tell, seems not to have followed Aristotle's footsteps closely; he dwells more, as did some other authors, on prepotency, and assumes that in particular cases the prepotency might have lain with the male or the female. Next we come to Alexandria, and to Herophilus who described the ovaries (διδυμοι), and the tubes (σπερματοκδι πόροι); but this more accurate anatomy did not reveal more physiology. So far as it went, indeed, it seemed in favour of seed in both sexes; but the Aristoteleans, magnifying the content of the σπέρμα, fancied that these female parts were but a "structural harmony," after the kind of the male mamma. It is notable that Falloppius, himself a master in this field of anatomy, and pursuing the same positive methods as Herophilus, scrutinised the ovaries and vesicles minutely in search of a seminal element and, finding none, also denied seed to the female. And we may suppose that Harvey, in holding the same opinion and denying that the ovaries, to which he attributed a rather fantastic function, were an equivalent of the testes, followed Falloppius. But to come to the pneumatists: Athenaeus, and Archigenes who followed him, seem to have been the last physicians of the period to rely upon Aristotle; they denied seed to the female, and Athenaeus seems to me to be even more dogmatic about it than Aristotle himself. Galen, however, definitely did attribute dynamic seed to both female and male. The old demur that the progeny were as prone to resemble the mother as the father, for Galen held no difficulty; he assumed that each sex afforded a seed endowed with both virtue and substance (δύναμις and ὕλη); and yet he betrays a curious uneasiness about it, for how is it, he candidly asks himself, that the female never conceives alone. As to the preparation of semen as a perfected product of the blood, in this respect Aristotle seems to have followed Democritus, Hippocrates, and Praxagoras in a speculation which reminds us of Darwin's idea of pangenesis; in the pneumatico-stoic opinion, however, the semen was sublimated from the hegemonic spirit in the heart.

Influence of Pneumatism on Medicine.

Of this kind, then, so far as these limits permit me to unfold it, was the doctrine of the pneuma, a metaphysical idea foreshadowing vital combustion. And pneuma, whether under this name or in refluent waves of aboriginal ideas under such names as the vegetable and animal souls, of the Archaeus, of van Helmont's vital principle, of the animal spirits of Descartes, of the motor nervous fluid of Stensen, of the animism which in the early eighteenth century sprang from chemistry, of the vitalism again which sprang from the doctrine of irritability, or of the transcendent vital quality beyond physico-chemical virtues entertained by some leading physiologists to-day—πολλῶν ὀνομάτων μόρφη μία—must, in so far as it is an imported entity, make a free pathology and an inductive therapeutics almost impossible. And meanwhile the humoral pathology had to be counted with, even by the pneumatists. If the pneuma might become hot and dry as in fever, cold and moist as in dropsy, too dense or too light with many consequences; or again, too quick or too sluggish: if it might be pent up, as in epilepsy and constipation, or, as in hysteria, imprisoned in the womb, so again the humours also might be crossed, or crossing, in one or more of the many possible permutations of dyscrasia. The Hippocratean doctrine was that health and disease depended upon the crases of qualities. That health consisted in a eucrasia was, it is said, an axiom of that spectral sage Alcmaeon of Croton; and the conception of diseases as modes of the many possible dyscrasias survived down to Galen and, by him regenerated, flourished as we know in a crude form through the Middle Ages; and in a sublimated form has yet a great part to play in pathology. These humoral doctrines the pneumatists did not abolish, but made their intricacies still more complicated, coiling them into a mesh which at present we have no leisure to unravel; curious as is the study of an intense mental hunger, with but a scanty harvest of knowledge, feeding upon itself. And not only in the first and second century A.D. in medicine, in Neoplatonism, and in the Christian Fathers, but again in the thirteenth century, and in the ingenious literature of the sixteenth and seventeenth century against which Sydenham led so masterly a revolt, we see history thus in principle repeating herself. It was well therefore that the empirical reaction initiated in the earlier Alexandria by Philinus the Coan and Serapion, narrow and ungenial as they seemed, and, more fruitfully and scientifically, the admirable surgery of the age curbed the extravagance of the pneumatic and other metaphysical opinions; and this protest it was which made the pneumatist sect strictly so-called, although backed by the Stoics, but a transient phase.[52] Indeed, its own greater men almost from the first had begun to hedge by a prudent eclecticism. And it is true that their central doctrine of the pneuma was less prejudicial to surgical progress, which they forwarded upon Alexandrian anatomy, than were their unbridled expatiations, a wasted or even a mischievous energy, in the field of inner medicine. That the pneumatist emphasised the dynamic side of physiology is true also; and that, like the methodist, he recalled attention to the solids of the body; yet, by personifying the pneuma as an indwelling and creative entity, he provoked a reduction of the functions of growth, work and excretion to a passive machinery worked by a demiurgical finger: thus the whole framework of digestion, for example, became for him a mere gizzard, a mill for mechanical contrition of food; and therapeutics became a magical checkmate of the malignant. Now the methodist, or at any rate the Lucretian atomist, before the formalist Themison, while animated no less by the dynamic idea, had regarded energy more truly as one aspect of a quick matter than as the demonic master and manipulator of an engine. And the sceptics of the day, on narrower if surer ground, were teaching, almost with the decision of Locke, that thought can only be built upon the functions of the senses. Even for Diogenes of Apollonia[53] phenomena, the pneuma having condensed into them, were but phenomena, not outside realities; and concepts therefore were fashioned wholly of the products of our senses. The defect of these critical schools, at any rate of the Empirics who did not realise that we see what we are trained to see, was, as I have explained, an intolerance even of the chaster Hippocratean reasoning on causes, and a repudiation of anatomy which reminds us of Sydenham's aversion from pathology. Difficult as it is then to define our distinctions between the later Herophileans and Erasistrateans, or even to contrast the persons and doctrines of the two great leaders, yet it would seem from the course of events, and from Galen's testimony, that on the whole Herophilus had more of the utilitarian bent, while Erasistratus was of a more speculative temper; for Galen accuses him and his followers of scoffing at the clinical school of Hippocrates in a manner which Galen regarded as unmannerly and cavilling. But probably, as I remarked last year, Erasistratus also scoffed not so much at Moses as at the Mosaic dogmatics; while for Herophilus Haeser vindicates some balance of observation and reasoning, some use of theoretical explanations. Celsus in his invaluable preface, while attributing to Erasistratus also some measure of the empirical temper, says again of this point of view that, although basing its practice upon the more manifest of them—

[51] See the eighteenth chapter of the "De Generatione Animalium"; and also the "De Anima." After these lines were written I read in the British Medical Journal (August 13th, 1910) a very able and interesting article, signed "J. W. B.," on Dante's knowledge of Aristotle's "De Generatione," and noted that in Dante's words we might observe a strong infusion of the pneumatic doctrine. I venture, however, with great respect to question if Dante's account of the accretion or supervention of the animal upon the plant soul can be interpreted as a "flash of insight" into our modern idea of the embryo "climbing up its own genealogical tree." His phrases seem to me to contain no more than we meet with not infrequently in ancient and medieval speculation, and we must beware of importing into them concepts of our own.

[52] I venture to repeat that Gomperz has liberally insisted that, whatsoever the inconsistencies within the faculty itself, this service for a more positive method and influence was one for which ancient philosophers were indebted above all to Medicine.

[53] Cf. Krause, loc. cit.

upon the *causas evidentes*—it did not refuse to consider obscure and remote causes: *causis obscuris omnibus, non a cogitatione artificis, sed ab ipsa arte rejectis.* So Jack Wilkes "was never a Wilkite." It would appear notwithstanding that the concentration of Herophilus upon present symptoms—such as the pulse for instance, on immediate or at any rate proximate causes, and, in common with his great contemporary, upon anatomy both normal and morbid, established a pragmatic bent which in the practice of his disciples, if not in his own, led to over busy interference, to much drugging, and to excess of venesection; while the Erasistrateans, as reflected in their disciple Asclepiades, reasoning upon wider and remoter causes also, and becoming sceptical of therapeutical prowess, pursued a more expectant method. That accordingly Herophilus abode in the four humours, while Erasistratus discarded or neglected them, if in part it explains the antagonism of Galen to the Erasistrateans, still carries with it more history than this. For if the humoral doctrine involved its disciples in a mess of pharmacy from which the Erasistrateans won their freedom, yet on the other hand it would seem it was this inclination from the juices towards a dynamic or pneumatist conception which gave countenance to the opinion of Praxagoras, conveyed by Straton, that the arteries contained air rather than blood—an error of momentous consequence. What Galen did afterwards was to force both empirics and methodists back to study anatomy, to scrutinise causation only too meticulously, and to restore and develop the elemento-humoral tradition; while in his physiology, under the guises of the psychical soul and of a divine teleology, he perpetuated some pneumatism. Thus, while phlegm was interpreted as moist, yellow bile as hot, black bile as earthy, upon these were worked in the three entities of the soul; the animal soul having its primary reception in the pulmonary veins. A great part of our difficulty in distributing these sources and phases of opinions lies in what was Galen's own misfortune likewise, that, rich as by tradition may have been his physiological and clinical inheritance, he, like ourselves, was deprived of historical sources; for even in his day the destruction of manuscripts—as, for one instance, in the siege of Alexandria by Cæsar—had been already disastrous. We know that in the time of Galen, and probably of Celsus also, the works of Erasistratus had perished; and still more unhappily certain histories of medicine under the names of Hermippus of Smyrna (Περὶ ἐνδόξων ἰάτρων), Andreas of Karystus, and of Histomachus were lost (Haeser). No insubstantial deliverance of medical tradition was notwithstanding handed down to the third century, if in a more impalpable form than of parchment, through Asclepiades, Themison, Archigenes, and many others over whom oblivion has cast her poppy;[54] and above all things the Hippocratic series of manuscripts had been preserved in other libraries.[55]

The brilliant progress of Alexandrian anatomy would in itself suggest that in morbid anatomy also advance was not wanting; although, in the early destruction of the records, and under the overgrowth of the later metaphysical cobwebs, much of it fell into oblivion. But that necropsies were then made for the investigation of disease is well known. For instance, a statement of Erasistratus has survived that in some cases of dropsy the liver was condensed, and as hard as a stone. In Alexandria pathological dissections were probably obtained without difficulty; in Rome the current prejudice against them was prohibitive, and so persisted even into the fifteenth century, when the Florentine, Antony Benivieni—the friend of Ficino and Poliziano—made it yield to his ardent importunities.

HYGIENE.

The hygienic and therapeutical doctrines of the pneumatists, and of the eclectic or "episynthetic" physicians who assimilated the more effective results of methodist, empirical, and other schools of the period, were of considerable interest and importance. The surgery of the school especially was excellent, and it is a matter of grave regret that of its records but little is extant. If in the light of recent researches our standard histories of the surgery of this period need revision on some points, yet on the whole it has been set forth almost as fully as the materials permit, so that I will not now dwell upon it. I will turn rather to the hygiene of the period, as of peculiar interest to us who at this moment are occupied with the medical aspect of education, to note the close attention this branch of the public service had received from the Greek physicians in Rome. Celsus, from the point of view of a Roman gentleman, gave some excellent hints on this subject; and the following interesting fragment of Athenaeus is preserved in Oribasius (III. 164): "*χρήσιμον δε ἡ μᾶλλον ἀναγκαῖον πᾶσιν ἀνθρώποις ἀπὸ ταύτης τῆς ἡλικίας ἅμα τοῖς ἄλλοις μαθήμασι συμπαραλαμβάνειν καὶ τὴν ἰατρικήν, καὶ κατακούειν τὸν ταύτης λόγον, ἵνα καλοὶ καὶ ἀγαθοὶ σύμβουλοι γενώνται πολλάκις ἑαυτοῖς τῶν εἰς σωτηρίαν χρησιμόν.*" For Athenaeus indeed medicine was even more than this, it was an integral part of a liberal education.

On airs—as of day and night, of hills and valleys, lunar and solar seasons, and of various climates—the pneumatists, as we should anticipate, laid great stress. Accordingly we find such airs described as moist or dry, hot or cold, dense or thin. Night air was cold and thick, and consequently apt to cause rheumatism, fever, and inflammation. I need not stay to interpret the warning that, of seasons, the air of autumn was the most dangerous; and that during these months one should never sleep out of doors. The air of towns was warm and thick, so that natives of towns were fat, and were sluggish in their secretions. The air of enclosed valleys was bad; and likewise the air of river flats and of marshy places. Inland air was said to be more wholesome than that of the seaside, an opinion derived perhaps from the malarious infection of estuaries, and of harbours, such as Ostia. Drinking water was to be filtered through porous stone or earth, but particularly to remove dirt and leeches.

Diels draws attention also to their careful adaptation of hygienic rules to the periods of the individual life. Still depending chiefly upon the reports of Oribasius and Aetius, which as regards Athenaeus, Agathinus, and Herodotus,[56] are fortunately copious, we find that the pneumatists regarded its course as of four stages—of infancy, of adolescence, of middle-age, and of old age. We shall note with particular interest that they discouraged all serious school work before the age of six or seven; then the child was to be taken in hand by a mild and kindly master, who would discipline the child by changes of work and play, carefully avoiding prolonged stress of either but encouraging him by emulation, finding for him a delight in learning, and remembering that severity or satiety engenders an aversion which in after life may never be overcome. From the age of 12, however, the work was made tougher, and the pupil led to feel his powers, and to put them forth in such studies as grammar. The master was to be well versed not only in intellectual matters but also in dietetics, in the wide range of exercises known as gymnastic, in the use of the bath, and particularly in the apportionment of the hours of sleep. Thus, as the boy grew up, bodily and mental development went hand in hand; and in adolescence, in order that every man should understand the conditions and promotions of a normal life, medicine and philosophy were introduced into the curriculum. Concupiscence was subdued in youth by gymnastics, and by the general discipline of mind and body. In maturity the generative function was to be approached with due sense of responsibility; and directions were given for the *παρασκευὴ πρὸς τὸ παιδοποιᾶν*. The sage council was given not to forget even in youth the prospect of old age and, as years wore on, to economise the efforts of body and mind, and to cut down the quantities of food; indeed, at all ages the food was to be reduced in warm weather. And with the exquisite greek sense of balance, even in physiology, and of the unity of bodily and spiritual function, they reminded us—for are not these lessons for all time?—that in a healthy old age we should seek to be wholesome not in body only, but gentle of soul also, high-minded,

[54] The reader will remember that the treatise of Celsus was either little known to the physicians of Rome in later generations, or was disregarded by them as the compilation of a Roman layman.

[55] As on Aristotle and Plato in philosophy, so in medicine transcripts and commentaries on "Hippocrates" formed the backbone of the tradition. Cicero refers to the writings of Hippocrates as well known. Galen, besides his other reverential services to the father of medicine, wrote, or proposed to write, a critical essay on the genuine and false treatises of the collection. If it was ever completed it is lost; but Mewaldt in an essay in Hermes (1909) studies some relics of it. The greater Empirics, such as Xeuxis and Heracleides of Tarentum, were loyally devoted to the great master.

[56] As, for instance, Orib. III., 107, "*ἐκ τοῦ Ἀθηναίου.*" For the ready reference to these passages and comments upon them I am indebted again to Wellmann (loc. cit.).

never tiresome, in sympathy and fellowship lifting up the young with the fulness of sweet lessons from the past. In the education of women, while a wholesome interest in political affairs was not denied to them, they were advised to concentrate themselves upon the arts of the home and family. Such, when divested of their necessarily crude biological hypotheses, was the ripe wisdom and sagacity of these great physicians, so near us and yet so far away.

THERAPEUTICS.

The remedial therapeutics of the Roman physicians between Celsus and Galen have not, in their fuller details at any rate, the same practical interest for us as their hygienic teaching. We may glance somewhat cursorily at a few of the means. In their eclectic and expectant methods, in the development of physical means of cure, and in some use of wine, we note that influence of Erasistratus and of Asclepiades upon the pneumatico-eclectic schools to which I have repeatedly invited your attention; but it is with less satisfaction that we turn to note the influence of the Herophileans in that increasing use of drugs, and of violent means such as emetics, clysters, purgatives, and venesection, which gave a certain grossness to the therapeutics even of Galen himself, and under his influence degraded medicine more and more till the days of Molière. Herophilus and his followers revered Hippocrates in lip-service, and, indeed, did much to preserve and elucidate his writings; but they never obeyed the spirit of his therapeutics, which were founded upon prognosis and upon respect for the functions of nature.

Asclepiades had, as we remember, carried physical therapeutics to lengths almost, or quite, absurd; as in his swings, succussions, and jolts. Therapeutical gymnastics had been admirably developed from the Hippocratean schools through Diocles and Praxagoras of Cos; but it is to be observed that not only by Asclepiades and Celsus but also before them, indeed from Hippocratean times, and more especially in the Coan than in the Cnidean School, the intemperate pursuit or profession of gymnastics was deprecated, not only as injurious to the health, but also as illiberal (*κακοτεχνία*, Galen). Thus by the more sagacious physicians there was a continual mistrust of the gymnastic schools.[57]

At present, however, I will speak only of the passive movements, of the massage of the period which seems to have been elaborate and refined. By four or six performers the entire body seems, often at any rate, to have been massaged at once; two performers manipulating the arms, hands, and fingers, two the trunk, two the legs and feet. The first stages were slow and gentle, the later became gradually quicker and severer. We may note with interest that gentle massage was practised in fevers, so long as there was no acute focal lesion; the tolerance of the patient of its degrees and durations being carefully watched. The amelioration which by this means they professed to obtain was attributed in part to refrigeration by the induction of sweat. It seems to me, Sir, that in some measure this practice is not unworthy of the consideration of this College. The fever lore of these ancients was, as we all know, enormous; as Wellmann says, and as W. S. H. Jones has exhaustively proved, it was a literature in itself.

And we are all well aware also that the cult of water springs and the bath literature of early times, before as well as after Epidaurus, was no less prodigious.[58] The ancient magic of wells, which developed into the Epidaurian combination of theurgic and therapeutic ritual, had in the times of which we are speaking become a separate resource. The Roman physicians seem to have ignored the Tiber Island. But we read of pure water baths, of saline baths ("which warmed the body"), of oil baths for cramps, pains, and retention of urine, of sand baths, and of sun baths.[59] Asclepiades, and after him the pneumatists, argued against the abuse of warm baths which, however appropriate in their degrees for debilitated persons, were not bracing enough in fevers, or even for use in health. Here we call to mind Musa's reputed cold-water cure of his august patient. Nurses were lectured for "boiling their children"; and bathers were warned against letting water into the ears, "which damages them." Mineral waters, of course, had their many natural virtues. Archigenes gives us the first rational classification of mineral waters which is extant: he divided them into the alkaline (soda), saline, aluminous, sulphurous, ferrous, cuprous, and bituminous; and elaborately explains their effects on the humoral hypothesis.

Wine.—The place of wine as a remedy is a curious story; in my Harveian Oration (1900) I touched upon it, but there especially as regards its outward application, even from the days of the Good Samaritan. Asclepiades wrote an essay *Περὶ οἴνου δόσεως*, an epochmaking work in its way, the contents of which may be gathered from Pliny[60] and Dioscorides,[61] amid paragraphs deriving from such recipe compilations as that of Sextius Niger. As I stated in my lectures of last year, Asclepiades, who was nicknamed "*οἰνοδότης*," taught the therapeutical value of wine, and discussed the virtues of its various kinds—the greek, the roman, and so on; but the advocacy of Athenaeus seems, from negative evidence, as from the lack of certain details in Pliny and Dioscorides, to have been inspired not directly by or from Asclepiades but to have been influenced by the tradition of Diocles, Praxagoras, and Mnesitheos; authors to whom those compilers do not allude. Athenaeus says that wine, when carefully used—used with attention to proper rules of symptoms, of doses, of dilutions, of hours—arouses the pneuma from its torpor, and, as Archigenes repeated afterwards, is especially useful in syncope. Now syncope was then said to consist in a loss of tone (*τόνος*), a vital quality to which the pneumatists attached much importance, and the state of which for the whole body they were wont to infer from the tone of the pulse. From a persistent acceleration of the pulse in fever, for instance, they inferred correctly that the remedy should be withdrawn.

Venesection.—But I need not say that of all the therapeutical means practised and discussed in those days the most ascendant was venesection; and concerning it the controversies of the schools were the most stubborn and acrimonious. In my lectures last year I noted the reserve of Asclepiades in respect of venesection; a means which, for good reasons, he did not withhold, but kept in hand for critical moments. Now the close attention of Athenaeus and the pneumatist school to the pulse gave no little importance to their teaching concerning this remedy. But the protest against the practice of venesection as a potent and a vulgar ally against disease in general carries us back into a much dimmer past. Not to detain you by a long retrospect on the sacredness of the blood—no unfamiliar subject in the Old Testament for instance—I may curtly remind you of this superstition in the semi-Oriental mysticism of Pythagoras; and so onward in medicine it influenced Empedocles and the Sicilian School, Philistion of Locroi, the Cnidians, and Chrysippus. If we may rely upon certain passages in the eleventh book of Galen (150, 197, and 252), Chrysippus stood prominently forth as an opponent of bleeding, and his deprecation was heeded more especially, so it was said, by one Medius, an uncle of Erasistratus, and by Erasistratus himself and his disciples. This forbearance was a little more remarkable in that the Erasistrateans, and indeed Chrysippus himself, clearly perceived the perils of plethora, but these they combated by diet. The objection to bleeding was formulated as an opening for the escape of the animal spirit (*πνεῦμα ζωτικόν*). Apollonius, a pneumatist of whom we know little, although indisposed to bleeding as a routine, contributed the interesting demur, that in plethora the permeation of the periphery by the *πνεῦμα φυσικὸν* was retarded. As reasonable persons, therefore, they accepted no formula but, before using the remedy, estimated the general conditions of the malady, the state of the patient as to strength and nutrition and so forth, and especially as to age and sex. Archigenes, however, advised that bleeding in some form was not inappropriate in plethora; and many of the school believed at least that by this means foul humours could be evacuated.[62] In fevers, however, they had

[57] On this subject the reader is referred to the admirable study by Juthner of Philostratos Ueber Gymnastik, Leipzig, 1909. (Philostratus lived soon after Galen.)

[58] The Alexandrian Greeks owed but little to the Pharaonic Egyptians, who were, however, as we gather from Herodotus (I. 193, 198, and II 35–37), at least hygienists. They had a State health service, and practised many ablutions of person and clothing, as did the Babylonians also. The honour of filth in person and clothing was left for medieval times. The Egyptians also vigilantly and ceremoniously protected their water courses.

[59] The reader who desires to know more of this history may be referred to the Second Book of Oribasius, chiefly compiled from the works of the distinguished pneumatist physician Herodotus, pupil of Agathinus.

[60] N. H., xxiii., 31.

[61] V. 7.

[62] It is interesting to note that in almost all schools of ancient medicine melancholia was attributed to toxic causes.

no doubt that to reduce diet, and at the same time to draw blood, was to exhaust the patient;[63] therefore, to prevent the inflammatory indraught of blood into the arteries in fever the master, after the Alexandrian tradition, bandaged the patient's limbs so as to keep the synastomoses closed, and thus to prevent the conflagration of blood and pneuma in the thorax. For we have seen that Erasistratus, to account for blood in the arteries, assumed certain more or less distal communications between the veins and the arteries, gates normally guarded or closed. On account of this meticulous shunning of venesection, though they limited rather than repudiated it, Galen waxed almost as hot against the pneumatists as against the methodists; but Celsus (52, 3) in his cool and shrewd way had said long before—in reference to Asclepiades, "*Sanguinem incisa vena mitti novum non est, sed nullum paene morbum esse in quo non mittatur, novum est.*" The pneumatists, or Erasistrateans, reasonably argued that in many cases local ought to be preferred to general bleeding, as by cupping, scarification, or leeches; and that in many cases even dry cupping or a cataplasm would suffice to draw off a congestion.[64]

EMINENT PNEUMATIST PHYSICIANS.

After this discussion of pneumatic doctrines, modified or masked, generation after generation from Alexandrian times onwards, by empirical, sceptical, stoical, and eclectic tendencies, and even by changes of name, and at length formulated for Medicine by Athenaeus in Rome, I propose to return, so far as the fragments will permit me, to the personal story. Of Agathus, and after him of Agathinus the Spartan, who lived in Rome under the Flavian Caesars, and were important links in the chain between Athenaeus and Archigenes, we know little; but it would appear that both of these physicians played a considerable part in the fusion of doctrines to which I have often referred, a fusion which made the name rather than the essential doctrine of the pneumatist short-lived. Greenhill regarded Agathinus as taking the lead in these eclectic or "episynthetic"[65] modifications: "Εκλεξάμενος τὰ αρέσαντα ἐξ ἑκάστης τῶν αιρέσεων." Archigenes, who a pupil of Agathinus, said of his master that he was accurate in all things, and ripe in experience. Still guided by three main clews of pneumatist doctrine—namely, the pulse lore, the fever lore, and the hygienic, pædagogic, and dietetic forms of therapeutics—we perceive at this period more explicitly the fusion of Pneumatism, Methodism, and Empiricism, with a younger and more liberal Hippocratic, or clinical, medicine.[66] This blend of old and new suggests to us progress, an orderly development of medicine; and we shall see presently that a solid, sagacious, clinical school, variegated indeed by some sectional dissent, survived, and superseded the arrogant domination and the sterile maxims of the later methodists, such as Thessalus. And yet we must admit that on the dogmatic or clinical side this evidence of sound development was accompanied not merely with a respectful appreciation of older doctrine, but with a mechanical tradition of form and letter such as seems to us to be contrary to the spontaneity of life. For although we are wont to suppose that the medicine of summists, of copyists, of large and literal transcripts, belonged to Byzantinism, and signified then the routine, if not of decrepitude at least of an unintelligent conservatism, yet we have seen that the era of scribes and summists must be carried back much farther than we had supposed, to a period not only far before Oribasius and Aetius but before Varro. And plagiarism was not confined to the scribes; even men of natural genius, such as Soranus and Galen, excerpted largely, literally, and anonymously; so did that imposing surgical phantom, Antyllus; and so, says Wellmann, did that no less considerable surgeon Heliodorus whom, on the slender relics that remain, I am disposed to regard as of still richer genius. In discussing, then, all these romano-hellenist medical writings, we must bear in mind the custom among them of lifting both terms and volumes of the literature one from another; and this without acknowledgment, unless when, happily for us—as often in Galen—controversial animosity goaded to personal attacks. That Celsus named his sources so generously may in the enemy's mouth be one more point of evidence that he was a layman! In the fragmentary and disconnected state of the records of the period then we cannot be sure whither, and how, many of these embedded remains are in their origin and order to be distributed. Any such distribution which, with the aid of far greater scholars than myself, I may now attempt, in order to distinguish individual authors, must therefore partake of much uncertainty, and be in its nature provisional; but in justice to the memory of Archigenes it must be attempted.

Archigenes and Aretaeus.—To appreciate Archigenes, one of the greatest of the physicians of this period, we must first discuss the place of Aretaeus, who, by name at least, is familiar to us all. And probably not a few of us, attracted by the story of the past, have perused, or at any rate dipped into, his treatise, so admirably rendered for English readers by Adams, and have been deeply impressed by his gallery of diseases—portraits select, succinct, deft in their handling, and speaking of character and experience. Galen, more diffused in generalities, never painted such telling pictures of morbid species. From it we have formed, and justly formed, a high opinion of the medicine of the age. This impression I say was just; but that Aretaeus in person justly deserved the honour is another matter. The ancients gave him no such meed. The author, who drops systematic pneumatism in his practice, which is on sound Hippocratic lines and probably moulded in some part upon Asclepiades, and interprets pneuma merely as *φύσις* in the Hippocratean sense of *δύναμις ζωτική*, or generative energy, yet by phrases here and there, such as his emphasis on *τόνος*, betrays his school. He seems to have lived under Domitian or Hadrian, but to have fallen into a long neglect. The first mention we have of him is in the sixth century by Aetius; then by Paul in the seventh; after then he sank once more into oblivion till the middle of the sixteenth, when the Greek MS. of a large part of his work was discovered, and was printed in Paris in 1554. It was now observed that the treatise was written in Ionic Greek; now the Ionic singsong in his day had become a literary fancy, and to use it in medicine was an affectation, even—so competent scholars assure us—an affectation so "grotesque" as to strengthen some suspicions of the writer's originality in other respects. Was the neglect of Aretaeus by the ancients because they knew him to be but a secondhand and archaistic scribe? It does seem probable that in Aretaeus the Cappadocian, who so far as we know never visited Rome, we find a conspicuous example of that prevalence of copying and recopying without acknowledgment which, not unknown among ourselves, then prevailed in the large measures I have indicated.[67] Delicate and complicated as is the task of tracing such stolen property from one obscure author to another, yet as out of it comes to light the figure of Archigenes of Apamea, of the time of Trajan, who, like Asclepiades, seems to have suffered unmerited eclipse, we must try, if on main lines only and by renouncing some of those impressions of form which we call the higher criticism, to make clear in summary[68] certain restorations and redistributions suggested by modern students concerning these records.

Of the confessed compilers Oribasius, who lived during the last three-quarters of the fourth century, was the chief; and of his collection about one-third is extant. The chapters on the poison literature are lost. We know, honest man, from his own references, that he swept into his net Dioscorides, Archigenes, Antyllus, Philumenus, Philagrius, Poseidonius, and Galen. About a hundred years later flourished another such scribe, namely, Aetius, and in his collection lies our main source of the poison literature, after Pliny. But Aetius, luckily, did not copy from quite the same sources,

[63] In more than one passage of Galen's XIth Book. See also Book X. 376.

[64] Which vein to open in a particular case or malady, in the elbow, in the ankle, in the temple, at the nasal angle, in the tongue, in the little or ring finger, and, not least, on which side of the body, was in the times of which we are speaking, and still more in the Middle Ages, often decided on fantastic reasons. Arteriotomy was practised occasionally by the ancients, but under what conditions is not precisely known.

[65] Not, of course, the philosophical school so-called.

[66] We may observe in the Pneumatist succession the continuous use of Methodist technical words, such, e.g., as *ἔνστασις*, a stoppage of the pores.

[67] We do not, of course, estimate these annexations by modern ethical standards. In ancient times written matter when published became the common property of the reading public, "*δεδημοσιώμενα τῶν καταβέβληται.*"

[68] In this summary I rely on Wellmann's Pneumatists, and on his article in Hermes, 1908; also on Daremberg's edition of Oribasius, and of Rufus.

nor quite the same things, as Oribasius; he borrowed from Asclepiades, and, so far as extant MSS. inform us, he made a larger use than did Oribasius of Philumenus. Now, who was *Philumenus*? Well, he too was an eclectic methodist and pneumatist of the generation of Galen (about 180 A.D.), and likewise a compiler after the spacious manner of Oribasius; but only some portions of his work, those contained in Aetius and Paul of Aegina, were known until Wellmann's discovery, in the Vatican, of 37 short chapters of his work, most fortunately with the names of the authors submitted to his scissors.[69] Philumenus again gathered his materials from somewhat different sources; so that these three compilers throw cross lights upon each other and upon their various sources, so that by comparing them certain identifications begin to appear. Philumenus has this particular value for us, that Archigenes seems to have been one of his principal sources. This inference first suggested itself to Wellmann while reading a certain chapter containing an antidote to viper venom, which he recognised as the antidote of Archigenes. Now Aetius, in all the diseases concerned, while similar to Aretaeus, is fuller, and presents also some peculiar differences; for instance, in respect of pleuro-pneumonia and empyema Aretaeus does not extend beyond Soranus. And in respect of headaches and of epilepsy the identification can be carried farther; for herein Soranus, and even Galen, and much later Alexander of Tralles, as well as Aretaeus, followed Archigenes. Not to detain you on points of cumulative evidence, I may say that in the divisions of matter, in the way in which certain drugs are selected and used, and so on, there are further coincidences which are very significant. The conclusion seems to be then, that Aretaeus was a copyist, as was Aetius; that they copied from some source common to both, and that this source was Archigenes, whom indeed Aetius happens to name. Wellmann, comparing them in parallel passages, declares that Aretaeus is just a servile copy of Archigenes, if not directly, then by the intermediacy of Philumenus; and this may be. But I would remind you that there is much verbal identity with other authors in Galen also; and if I may venture to demur to a judgment of this distinguished scholar it would be that the agreement in many such passages is substantial rather than literal; and in a broader sense I would urge that similarity of terms, and even of phrases—"literary universalities"—does not necessarily convict an author of plagiary. Phrases which become current in one period fall out of another. In the medical journals of to-day we may readily note the professional dialect and shibboleths of our own time, especially in the writings of the less literary of our brethren. And thus, under the Roman Empire, although, for instance, Aetius did not copy Oribasius, yet in many places there is much similarity between them and no little verbal identity. Nevertheless, it seems more than probable that, whether through Philumenus or not, Archigenes was the main source of Aretaeus; and that Philumenus, who reproduced Archigenes, was in his turn the main source of Aetius and no inconsiderable source of Oribasius.

However, there is yet one more of these compilers to whom, if you will forgive me, I must refer—namely, one *Alexander*, of whom I, at any rate, know nothing except the remarkable treatise, easy to lay hands upon, which stands first in Ideler's Collection. It consists of two sections, one on Problems and one on Fevers; and with this it is that we are now more particularly concerned. For this fever chapter is in close conformity, often in verbal identity, with Galen's writings on fever, the pathology of which, with some qualifications of his own, he drew from pneumatist sources. Now in both Galen and in Alexander we find fever divided into two categories, thus: (1) as to severity, the πυρετοὶ μέγαλοι καὶ μικροί; (2) as related to the three kinds of bodily substance respectively—the dense, the moist, and the vaporous[70]—that is to say, quotidian, septic, and hectic. But on turning to the same passages in Alexander we find a third category—as to "rhythm"; namely, slow, quick, intermittent, and continuous; though it is added that as the motions of heat are infinite so these rhythms glide the one into the other. And, in respect to those kinds of bodily substance, he goes on to say that the harder its constitutional substance the less is the body swayed by the fever, and the less the sympathetic propagation of its motions through the system: thus a quotidian is brief because it vibrates only in the rarest substance of the body. Now this additional matter Alexander must have got from the large work of Archigenes, mentioned by Galen, Περὶ τῆς τῶν πυρετῶν σημειώσεως, from which he had made a somewhat larger excerpt than had the others from the common source to which they all betook themselves. Now fortunately, Galen (VIII. 203) gives the title of an important pathological work of Archigenes; and Oribasius (II. 146) that of his work on therapeutics—namely, Τῶν ὀξέων καὶ χρονίων παθογνωμικά; and Θεραπεία τῶν ὀξέων καὶ χρονίων παθῶν, respectively; both apparently in four books; and these titles, as we shall remember, correspond to the four books of Aretaeus On the Symptoms and On Treatment of Acute Diseases, and On the Symptoms and On the Treatment of Chronic Diseases.

Now we have the titles of two others of the more celebrated treatises by Archigenes—namely, the Περὶ τῶν κατὰ γένος φαρμάκων and the Περὶ τοπων πεπονθοτών, (in three books) to which Galen gives high praise. The work on the seats of disease would have been an invaluable document for the historian. We are told that in it Archigenes, with a genuine clinical instinct, inquires if from a comparison of the varieties of functional perturbation, or symptom groups, seats of disease could be inferred; if there be, that is, a signal group for each seat? For example, if we observe this series—orthopnœa, rusty or dark and livid or frothy sputum, fever, pain in the side, and a rapid pulse—we infer a peripneumony. Dyspnœa is common to many maladies, it is true, but we interpret it by its associates; as in this case by fever, the kind of sputum, and so on. Galen (De locis affectis) scoffs at a narrower argument of his, that the seats of disease might be discerned even by several kinds of pain; apparently it did partake too much of the nature of a logical exercise, for Galen complains of its newfangled notions and terms; but nevertheless the method was a sound one. Moreover, upon it Archigenes seems to have built another fruitful clinical idea, that of sympathetic parts, and primary and secondary symptoms. Thus he pointed out how disease in a certain part might betray itself by pain or disorder in a distant part, not itself diseased. He instances, and very appropriately, confusion of vision caused by a disorder seated in the stomach. These views, and the seat of the hegemonic pneuma in the heart, Galen contested; though on the whole treating his great predecessor with respect, and paying him the dubious compliment of copying from him extensively, often without acknowledgment. For example, Galen's description of that notorious disorder the πνῖξ ὑστερική—the hysterical suffocation, is identical with that of Aetius, as are both with that of Philumenus the plagiarist or copyist of Archigenes.[71] This description was that the restless uterus attacked the heart through the arteries, the liver through the veins, and the brain through the nerves: the simulation of death was described; and the cause was attributed to a chill to the pneuma, a pathology opposed to the more rational notion, of Soranus, of an inflammation of the womb, which engendered in the cavity a cold and moist phlegm; in quantity no doubt small, but, as he urges, how minute may be the venom of a snake or of a mad dog. Now, in commenting upon this account in Aetius, Valentine Rose proved, by facts with which I will not trouble you, that Aetius did not copy from Galen, but, as we have seen already, from Archigenes, the common source of both writers.

On other subjects, as concerning the cynanches, for instance,[72] and certain drugs and their uses, a like correspondence is notable, but I will touch on two more coincidences only—namely concerning elephantiasis and concerning the hellebores used in the treatment of it.

[69] This discovery was one of the many fruits of the formation of the preliminary catalogue for the Corpus by the associated academies. Unfortunately, a vast pile of MSS. thus revised and catalogued has brought in little so far; such matter as 150 indifferent MSS. of the Aphorisms; 100 of the Prognostics, and so on, with quantities of Arabian, Syrian, and Hebrew translations. So it may prove that for Galen we shall have little better than the Ed. Pr., or for Paul than the Aldine. And Aetius is complete only in the Latin version of Cornarius. There was a sad loss of MSS. in the fury of early printing. (See VIth vol. of Pauly-Wissowa; art. on Dioscorides).

[70] στερεά, ὑγρά, and ἀερώδης οὐσια.

[71] We may conveniently regard Galen's works as consisting in part of his own original observations and thought; in part of fugitive pieces concerned with the questions of the day; in part of compilations.

[72] Vide, e.g., Die Halskrankheiten bei d. altgriechischen u. römischen Aerzten, von J. Weigel, Leipzig, 1907.

Elephantiasis was so hideous, so alarming, and so conspicuous a disease that, if prevalent, it could not escape observation. We may recognise this horror in its various names, such as leontiasis and satyriasis. On the evidence of silence then we may assume that elephantiasis did not appear in Italy until about the time of Themison and Celsus. The first description of the disease, so far as we know, was written in the third century B.C. by Straton, a description handed down to Themison through his master Asclepiades. Of this disease and of its treatment Aretaeus gives a full report;[73] and Wellmann, comparing it passage by passage with that of Archigenes as preserved in Aetius, points out that in this chapter again Aretaeus was a plagiarist of Archigenes. The treatment of the disease was also identical in both—namely, venesection at the elbow, hiera, hellebore, whey, viper preparations; and—externally for the tubercles, the unguent was similar.

The hellebores were in occasional use by physicians in more ancient times. Herophilus, on whose bent for pharmacy I have already insisted, seems to have pushed this use of the drugs in some opposition to Erasistratus; and under Themison, Archigenes, Rufus, and others they came into the common use which is familiar to all classical scholars. Anticyra, Sicily, and Galatia produced the best kinds. Hellebore was used chiefly perhaps for melancholia (which, as I have said, was generally, or always, regarded by the ancients as a toxic disorder), for other insanities, and for pains in the head. Now Aretaeus further appropriates from Archigenes full directions for the use of the herbs; the white hellebore to act especially upon the upper bowel, the black on the lower; and if a prompter action were required the herbs were to be cut very fine. They were used also as urgent emetics. In spite of the prudence of Asclepiades in therapeutics—a prudence and reserve I dwelt upon last year—and the large development of the physical methods of treatment, yet under methodists and pneumatists alike reckless attacks upon disease by powerful drugs prevailed more and more; and unhappily the influence of Galen did little to discountenance them. Emetics were used by the Hippocrateans more rationally, and in moderation by Asclepiades and Celsus also, who advised them in bilious constitutions, and for certain chronic diseases. Asclepiades indeed gave warning that abuse of emetics led to loss of appetite, atony of the stomach, indigestion, and emaciation. Nevertheless, vomitives obtained their vogue under the Empire, and as an instrument of gluttony, became almost habitual. These agents were many in number, ranging from a feather in the pharynx to a pound or a pound and a half of radishes in a horrible mixture with honey, salt, and vinegar; the oxymel of squills being another mawkish alternative.

While referring to the use of hellebore in insanity I may mention not inappropriately that on the treatment of this class of disorders Archigenes seems to have held opinions of remarkable enlightenment. Seeing the priests of Cybele scampering, and flagellating, and cutting themselves after their manner, he said "they are insane, do not leave them to these bloody gods of the East, send them to me." And his therapeutics was no less enlightened, for he fed up the maniac and soothed him with music. What would Bedlam have thought of this eccentricity!

Archigenes, as reproduced by Aretaeus, had a considerable knowledge of the veins and ducts of the liver, and wrote well on phthisis, and on diabetes which was regarded as a melting down of the flesh into urine—a sort of runaway dropsy. And of the anatomy and diseases of the nervous system his knowledge was considerable; for instance, he seems to have been the first to show that hemiplegia falls upon the side opposite to that of the cerebral lesion; and moreover to attach the aura to epilepsy. In his description of tetanus Haeser thinks a note of cerebro-spinal meningitis is to be detected. He recognised also the glandular nature of the kidneys, of the testicles, and of the mammæ. One remark of Archigenes might, after the lapse of all the centuries, come as a fresh light to the modern examiner. "What we need is to be fertile in expedients, not to be always paying attention to the writings of other people."[74]

[73] It is a curious feature in Aretaeus (Ed. Adams, p. 123) that he describes at length the elephant from which the disease took its name. Why? As a transcriber? Oppian gives this same description, one copied, it is said, by both writers from Amyntianus' Περὶ ἐλεφάντων; a book I find (in Smith's Dict.) is referred to by a scholiast on Pindar.

[74] "χρὴ δὲ καὶ αὐτόν τινα συνευπορέειν, μὴ πάντα ἀλλοτρίῃ ξυγγραφίῃ προσέχοντα τὸν νόον."

The surgery of Archigenes, whose fame, says Dr. Withington, was no less honourable as a surgeon than as a physician, and that of other Eclectic physicians of this period, presents a very fair story. The ancient Greeks shrank from mutilation; and amputation, mentioned by the Hippocratean physicians only in gangrene, as a subsidiary aid, seems, even in Alexandria, to have made no great progress; for Celsus also regarded it as a last sad resource in gangrene; yet by the time of Trajan, under Archigenes, amputation had become a recognised procedure for ulcers, growths, injuries, and even for deformities. The limb to be removed was bandaged, and a tourniquet was placed above the line of severance; or sometimes the chief blood-vessels were first cut down upon and tied, and the smaller tied, or twisted, during the operation,[75]—"transfixing them with a sharp hook and twisting them round and round and closing them by this twisting"—a proceeding of which there is no trace in Hippocrates, nor apparently in the earlier Alexandria. These good methods were afterwards obliterated by the bad fashion of the searing iron. But we know that Galen used the ligatures, and where the shop was at which he bought them. Moreover, as we noted under Soranus, the whole field of surgery had come under a more intensive cultivation. Still, if it be true that in Alexandria capital operations had not made much way, yet by the traditions of Apollonius of Kition, of Lysimachus of Cos and other Hippocratean commentators, of Apollonius Mys (a Herophilist from Alexandria), of Dioscorides, and especially of Philoxenus, we learn that nevertheless in that anatomical school surgery was carried actively forward; for instance, in cutting for stone and operating for hernia, operations which, before and after the prey of specialists and adventurers, seem then for a while to have been undertaken by the general surgeon; and by Heliodorus resection of the long bones was performed. How much of the more advanced surgery under the Empire was due to Romano-Greek physicians, as, for example, to Heliodorus and to that tantalising shade, without local habitation, Antyllus—a personage who probably owed much to Heliodorus but of whom we have little more than a glimpse in Oribasius—and how much of it flowed derivatively from earlier sources we cannot definitely say; but the progress seems to have been substantial and largely original.

Out of such fragmentary and allusive records as I have tried to stitch together, recent historians of medicine, and Wellmann especially, have endeavoured to reconstruct the figure of the great eclectic pneumatist, of methodist origin, Archigenes of Apamea; a figure not wholly eclipsed in the transit of Galen, for in the sixth century his memory is still revered by Alexander of Tralles as θειότατος εἴπερ ἄλλος. That Juvenal speaks of him as a fashionable practitioner need not derogate from his merits, as we pleaded in the life of his greater predecessor Asclepiades, and as we might have to plead for fashionable physicians of our own day, who, wise men as they are, do not disdain empirical and persuasive remedies when no arm of precision is at hand. Archigenes seems in character to have been a blend not only of several schools of doctrine but also of several complementary qualities: of theorising proclivity, yet rational in methods and technically sound in practice. To his clinical insight the fruitful distinction between primary and secondary disorders, and the indication of localising symptoms, which I have quoted from Aetius, is strong testimony. If, on the one hand, it appears from Galen's respectful criticism, and from other witness, that, after the fashion of the pneumatists, he was in preciosity of language and in sophistical dialectic something of a pedant, yet, on the other hand, he did much to deliver medicine from the cramping influence of the methodist common forms based upon an abstract principle, like the "homœopathic" formula which in our own day became for a while so dear to that most theoretical of creatures the "practical" man. Nay, if besides he seems to have fallen in with the use of amulets and such like, probably it was as a tolerant and humorous observer of the foibles of mankind, and of the magical influences of faith, rather than as a charlatan or a sorcerer.

I have said that to enter upon the poison literature would in this course be impossible, for in its biological and pharmaceutical aspects it would require a lecture for itself alone.

[75] Vide Daremberg and Bussemaker's edition of Oribasius, excerpts from Heliodorus' great Χειρουργούμενα in five books; and notably the passage "περιστρέψαντες πολλάκις καὶ ἀποτυφλώσαντες ἀντὶ διὰ τῆς περιστροφῆς."—Lib. L. c. 4.

Such a chapter may be added to these lectures hereafter; but in conclusion I would indicate the place of Archigenes in this current of medical history. We have seen that Philumenus, in his Περὶ τῶν ἰοβόλων ζώων καὶ τῶν ἐν αὐτοῖς βοηθημάτων, drew largely upon him, as he did upon less eminent men of the school of Athenaeus and Soranus; and this not least in respect of poisons and their antidotes. Our tradition of the poison literature, more or less mingled in its course with that of cosmetics, begins with one Apollodorus of Alexandria (*c.* 300 B.C.); and thence in dark volume it flowed through Nicander, Philinus, Andreas, and that remarkable man, a Herophilean turned empiric—Herakleides of Tarentum. Krateuas, who seems to have worked under the patronage of Mithridates Eupator, is a very important link of this chain [76] It is with Krateuas that we enter upon the Attalid and Mithridatic period of this art and mystery, on which the *locus classicus* is the twenty-fifth chapter of Pliny's Natural History; and so to Dioscorides, to Philumenus, to Aetius who borrowed from Philumenus, and to Galen. Thus at second hand Archigenes became a main source of this sinister lore for the Middle Ages, and for the papal and ducal circles of the Renaissance.

In these lectures, Sir, if I have failed, and with but our present resources we may hardly succeed, to bring the physicians of Rome out of chronological tables and to present them in living portraiture; yet if in any subordinate degree I have made some fair endeavour to illustrate the inner movements, and to read the genius of those variously gifted races of whom Roman Medicine was engendered—the dreamy Sicilian, the positive and sagacious Greek, the subtle and daemonic Oriental which, blended in Alexandria, inspired the motley players who walked the stage of our art and mystery at the feet of the imperious mistress of the world; if in any fair measure I have done this my labour and your long suffering, for which I gratefully thank you, may have been not wholly in vain.

A CASE OF MULTIPLE MYELOMA,

WITH SOME OBSERVATIONS ON THE NATURE OF THE "BENCE JONES" PROTEIN FOUND IN THE URINE.

BY OWEN T. WILLIAMS, M.D., B.Sc. LOND., M.R.C.P. LOND.,

HONORARY ASSISTANT PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL; LECTURER ON PHARMACOLOGY, UNIVERSITY OF LIVERPOOL;

AND

E. R. EVANS, M.R.C.S. ENG., L.R.C.P. LOND.

With a Pathological Report on this and Another Case

BY ERNEST GLYNN, M.A., M.D. CANTAB., M.R.C.P. LOND.,

LECTURER ON MORBID ANATOMY AND CLINICAL PATHOLOGY, UNIVERSITY OF LIVERPOOL; PATHOLOGIST TO THE ROYAL INFIRMARY, LIVERPOOL.

THE rarity of the condition in which multiple myelomata are associated with the peculiar protein in the urine described by Bence Jones [1] merits the publication of any cases which may be observed. A summary of the cases which had been recorded up to 1905 was given by Moffatt [2] in that year. In the case described below, which is a striking example of the disease, an attempt was made to elucidate the nature of the Bence Jones protein; and it was found that the protein in the urine, while giving the characteristic tests from day to day, varied at times in its composition. This would tend to show that the different opinions recorded by various observers may be due to the fact that the bodies found in the urine are derivatives of one common body, which derivatives may be present in varying quantities from time to time, not only in different cases, but even, as in this one, in the same case. The pathological report appended shows also that the different pathological findings of various workers are more apparent than real.

CASE 1.—The patient, a collier, aged 30 years, had always been a healthy man, and had had no illnesses previous to this one. He worked in the mine until Jan. 10th, 1910. When first seen on Jan. 11th he stated that he had not been feeling well all the winter. He had felt weak, having occasionally had pains in his chest and between his shoulders at various times during that period. When first seen he complained of weakness and of a very poor appetite. Mr. Evans, who had known the man for some time, found that he had wasted very considerably. Over the right fifth rib on the inner side of the nipple line there was a prominence, but no thickening of the rib could be felt. The tongue was thickly coated, and there was marked constipation. The urine gave a precipitate on warming which was not dissolved by the addition of acetic acid. During the next 12 days the patient became weaker, there was marked anorexia, and no change was observed in the chest. On Jan. 22nd Mr. Evans and Mr. C. E. Morris of Holywell examined the case together; a careful examination was made, and the whole of the spine was carefully investigated. There was no kyphosis or scoliosis, and nothing could be found to explain the protrusion on the rib. He was still unable to take food, and the tongue was very dirty.

On Feb. 8th some rigidity in the upper dorsal spinal region was observed, and the patient was too weak to get out of bed. On the 9th he was emaciated, sallow, and appeared very ill. The expression was anxious. The skin was loose and inelastic; the muscles were all soft. The mucous membranes were pale. There was no cyanosis, œdema, or jaundice. He was lying on his back with his head thrown back nearly as much as is shown in the photograph which was taken 18 days later. (Fig. 2.) The thorax, apart from the prominence over the fifth rib, was of normal conformation and moved freely. Apart from a few râles at both bases, no abnormal physical signs were detected in the chest. The abdomen was flat and moved normally, but the right rectus was quite rigid from the costal margin to the umbilicus. The heart was normal and the blood pressure was 130 mm. Hg.

There was no pigmentation of the skin or mucous membranes, and no enlarged glands could be felt in the neck, axilla, or groin. The tongue was coated with a thick brown fur. The bowels were constipated and some fæces could be felt in the sigmoid. Examination of the blood showed nothing abnormal. An examination of the motor system showed weakness of all the muscles, equal on the two sides. The small muscles of both hands seemed more wasted than the other muscles, the wasting of the thenar and hypothenar eminences being most marked. As he had been at work as a miner to within a few weeks of this examination this wasting was looked upon as being of special significance. The sensations of touch, temperature, and pain were normal over the whole body. The retinal fields were normal. The knee-jerks on both sides were exaggerated, more particularly the left. The ankle-jerk was obtained on the left side, but not on the right. The left plantar reflex was of the extensor type, though not slow; the right was flexor. Wrist, triceps, and jaw jerks were not obtained. The cranial nerves were normal. Standing up with assistance, he held his neck quite rigidly, the head being thrown slightly backwards. There was no scoliosis. The above signs were explained by the findings in the upper spinal region. The spinous ligaments between the last cervical and first dorsal, and between the latter and second dorsal vertebræ, were far less resistant than in any other part of the spine, and pressure over this region caused pain which was local, and not referred to any other part. Careful examination showed no area of anæsthesia over the area supplied by the lower cervical and upper dorsal segments of the cord. The urine of this day showed the characteristic reactions mentioned later, and a diagnosis of multiple myeloma with Bence Jones protein in the urine was made.

On Feb. 12th, on examining the ribs the first on the right side and the second and third on the left side fractured, and crepitus was afterwards observable. On the 18th the sternum fractured spontaneously just below the manubriogladiolar junction, giving rise to marked deformity as shown in Fig 1. On palpation in the second left intercostal space a well-marked thrill was felt, and a loud murmur could be heard on holding the ear near the chest wall, due presumably to the pressure on the pulmonary artery, neither thrill nor murmur being conducted into the neck. The pulsation of the great vessels could be easily felt through the chest wall. The urine passed on this day was quite milky in appearance. On the 19th the left sternoclavicular joint was disorganised, the ligaments being apparently loosened, and the inner end of the clavicle could be

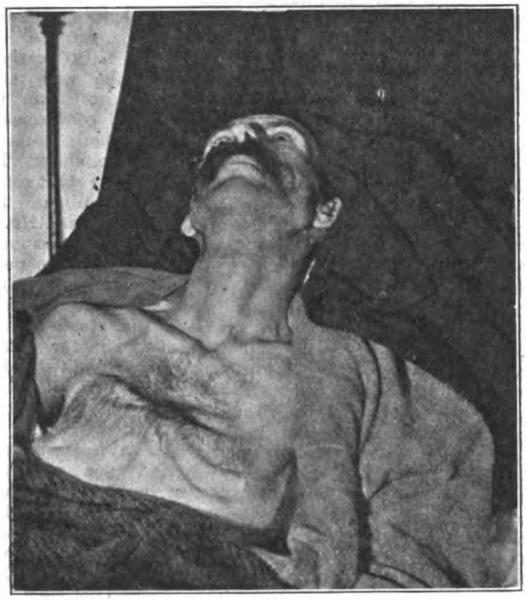
[76] Vide Krateuas, von M. Wellmann, Berlin, 1897.
[1] Philosophical Transactions of the Royal Society, 1848.
[2] THE LANCET, Jan. 28th, 1905.

easily moved in a circle of about an inch radius. On this date Dr. T. R. Bradshaw, who had had the unique experience of seeing five of these cases, saw the case with us, and he stated that clinically it conformed in every detail with the other cases which he had seen.

On Feb. 27th the patient was in much the same general condition, except that the appetite was much improved, but by this time the first, second, and third ribs on both sides were very markedly altered. They were soft and easily gave way before pressure. The photographs illustrating the condition were taken on this date. (Figs. 1 and 2.)

On March 1st the left sterno-clavicular joint was completely disorganised, and the inner end of the clavicle was drawn up into the neck by the sterno-mastoid muscle. On the 5th the patient lost the use of his legs completely, and also all sensation below the level of the loin; by the 7th there was complete loss of control of both micturition and defæcation, and death ensued on March 10th. Unfortunately a post-mortem examination was not permitted, but a piece of rib was allowed for examination.

FIG. 1.



Showing sinking in of sternum with alterations in the ribs.

The Urine.

On Feb. 11th the urine gave the specific reactions of the Bence Jones protein. On warming after the addition of acetic acid there developed at 52° C. a milky, then heavy precipitate, which disappeared almost completely at 95° C. The acetic acid gave no precipitate in the cold. On adding nitric acid a heavy precipitate formed which was soluble on warming and reappeared on cooling. This could be repeated several times. Repeatedly saturated with ammonium sulphate and well washed with the same fluid the precipitate, which dissolved in either dilute sodium chloride or water, gave the biuret test. It gave the test for loosely combined sulphur, and the potassium ferrocyanide and acetic acid test. The hydrochloric acid test (Bradshaw's test) was negative. The dialysed urine gave the same reactions. For the first few days the urine was passed quite clear, but later it became turbid and then milky.

The nature of this protein has given rise to a great deal of controversy. Bradshaw, as the result of examination of the urine of ten cases, states that it is an albumose. Magnus Levy, who isolated the protein and obtained it in a crystalline form, states that it is nearly related to a genuine albumin. Cohnheim considers it a coagulated albumin. Lindeman concludes that, while it cannot without objections be put in any group of proteins, it is nearest the true albumins.

In the various cases recorded the properties of the substance found have differed so much that either they were different bodies or were not tested pure.[3] That the proteins found can differ even from day to day is shown by the fact that the second specimen examined from the case under consideration (on Feb. 13th) gave a well-marked precipitate with cold acetic acid. A specimen of this precipitate was obtained from 500 cubic centimetres of urine, purified, and found to contain a carbohydrate radicle and no phosphorus; it therefore being a mucin. The reactions varied slightly from time to time, though on most days the nitric-acid test, coagulation temperature, loose sulphur, and "salting out" tests were quite typical. On Feb. 19th a dialysed specimen gave the hydrochloric-acid reaction quite typically, and no precipitate with acetic acid in the cold.

I then decided (after finding different reactions on two successive days) that there was probably a mixture of proteins in the urine, or that a common body was being split up differently from day to day. The dialysed specimen which gave the hydrochloric acid reaction was kept in an open vessel for two days, after which the reaction was much less marked. It then gave a precipitate with cold acetic acid (2 per cent.), which it had failed to do before.

FIG. 2.

Showing position in which head was constantly held.

This precipitate was phosphorus-free and contained a carbohydrate radicle. The probability was therefore that in this case there was a conjugated protein present, which under certain conditions resolved into other bodies, one of which was a mucin. Mucin and allied compounds belong to the group of glyco-proteins. These proteins occur in the tissues conjugated with chondroitin-sulphuric acid. An attempt was made to separate chondroitin-sulphuric acid from the protein, but none was obtained.

In the accompanying table there are the results of two days' complete analyses of the urine, which were performed with a view of obtaining some indications on which to work. It will be observed that there was an increased excretion of calcium and diminished chloride excretion.

Analysis of Urine in Case of Multiple Myeloma

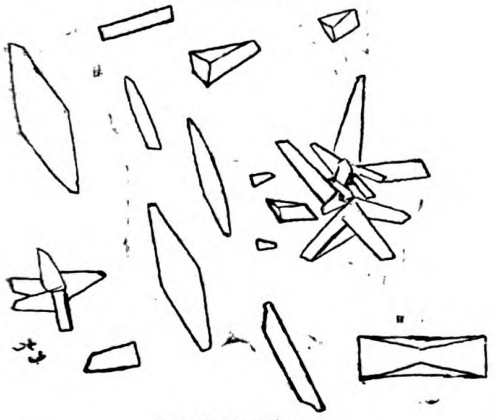
[3] Emerson: Clinical Diagnosis.

The most characteristic feature observed was the marked change in ethereal sulphate excretion, it being normal on the first occasion and markedly diminished on the second. This observation, coupled with the fact that the Bence Jones body contains loosely combined sulphur, suggested that the body might have some relation to the proteins which have recently been isolated from bone containing a high sulphur content. Loebisch, Gies,[4] and others have isolated a substance from tendons which does not differ from true mucins in its properties, and Gies has prepared an identical substance from bones which he calls "osseo-mucoid." It also possesses a high sulphur content and contains likewise a paired sulphuric acid, thus resembling a chondro-mucoid. It is obvious from the history and the photographs that in this case both tendon and bone were being rapidly broken down, and the probability of their derivatives being found in the urine is not unlikely.

The marked variation in the excretion of ethereal sulphates, with a protein in the urine containing loosely combined sulphur, led us to study the relationship between these two conditions, but unfortunately before this could be completed the patient died. On Feb. 18th from 500 cubic centimetres of urine 0·4 gramme of the protein was obtained in a pure condition. It contained 10·5 per cent. of sulphur. On March 2nd 0·3 gramme of protein was obtained, and it contained only 0·55 per cent. of sulphur. The variability in the nature of the protein found is thus obvious. It is of interest to observe that with this change in the nature of the protein there was a variation in the output of ethereal sulphate, on the first occasion there being practically no ethereal sulphates in the urine, and on the second occasion there being an excess. In view of the fact that the case terminated before these observations could be completed, it would be unwise to draw any fixed conclusions, but it is of extreme interest to find that in a disease where the bones and tendons containing chondro-mucoid are being rapidly broken down, proteins of a similar nature—in that they contain a carbohydrate radicle and a high sulphur content—are found in the urine. Two other cases of bone disease which were investigated at the same time revealed the presence of the mucin-like body, but they did not show any of the other reactions.

Another unusual feature in the case was the discovery in the urine of a crystalline form of sodium urate which is

FIG. 3.



Crystals of sodium urate.

shown in Fig. 3. These crystals are of interest in relation to the increased calcium katabolism.

We wish to thank Professor Benjamin Moore for his valuable advice and suggestions; also Miss Tozer for the drawing of the crystals of sodium urate.

Summary.

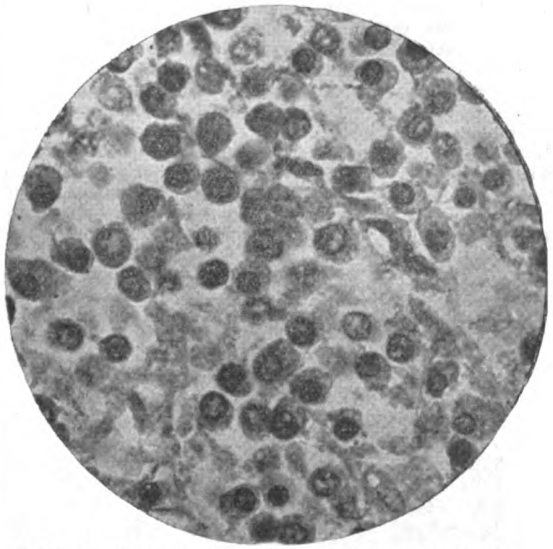
1. The protein found in this case gave on most occasions the characteristic reactions of the Bence Jones protein.
2. The reactions of the protein varied from time to time.
3. On all occasions when a thorough examination was made the protein yielded a phosphorus-free carbohydrate-containing radicle.
4. The percentage of sulphur in the protein was found to be different on two occasions.
5. This variation was found to be synchronous with an alteration in the output of ethereal sulphuric acid.
6. A possible explanation of these findings is that the chondro-mucins of the bones and tendons are broken down in different degree at various stages of the disease.

Report by Dr. Ernest Glynn.

A piece of rib 2 inches long containing a myelomatous tumour was fixed in alcohol, and portions which did not require decalcification were cut in paraffin and stained in hæmatoxylin and eosin, Unna's polychrome methylene blue decolourised with glycerin-ether mixture, and in Pappenheim's pyronin-methyl-green.

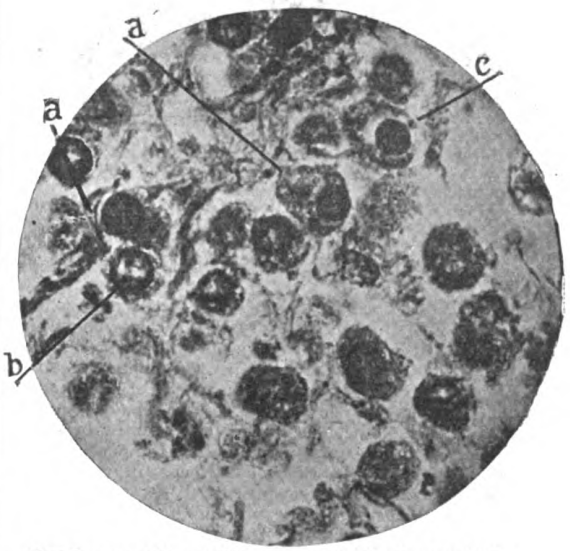
The tumour was composed of masses of cells, some of which were almost round, but the majority oval or even pyriform. (Figs. 4 and 5.) The cells varied in size; the

FIG. 4.



Section of myeloma, Case 1. × 600, showing cells of plasmacytic type—i.e., oval or pyriform cells with eccentric nuclei. Note also delicate stroma.

FIG. 5.



Case 1, same section × 1200. Note in addition to ragged cytoplasm (granuloplasm) and the delicate stroma—*a*, eccentric nuclei; *b*, wheel-shaped nucleus; and *c*, perinuclear halo.

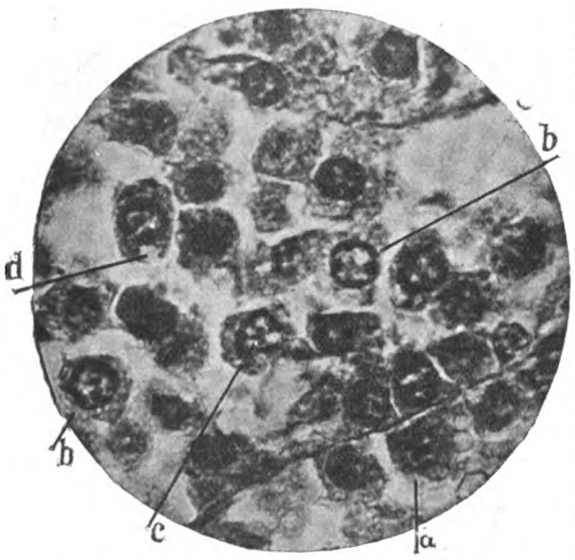
average measurement in the long axis of 12 complete cells was 8μ, the maximum was 11μ, and the minimum 5·5μ. The cytoplasm was basophilic, for it stained characteristically with pyronin and with polychrome methylene blue. In very

[4] Mann: Chemistry of the Proteids, 1906, p. 41.

thin sections it was ragged and almost granular (granuloplasma of Unna), but without real or specific granulations, also definitely vacuolated, and sometimes retracted from the circumference of the nucleus to form an unstained perinuclear halo. The nucleus was usually eccentric. It was round or slightly oval, and varied in size from 4 to 6·5μ, the average being 5μ. The chromatin stained well and tended to collect in masses at the periphery of the nucleus, while near its centre there was often a nucleolus coloured bright red with pyronin. A considerable number of the nuclei were somewhat shrunken and show hyperchromatosis, while in a few there was definite pyknosis; complete karyolysis was occasional. Some cells contained two, rarely three, nuclei, but without mitotic figures. Neutrophil myelocytes were very rare. The tumour cells were embedded in a delicate, scanty, fibrous-like stroma containing an occasional spindle-shaped nucleus. Blood spaces were few.

As pointed out by Kaufman,[5] Christian,[6] Ledingham,[7] and others the tumour cells in multiple myeloma have been classified by various observers into three main types: (*a*) myelocytic, though the granulations are not always so completely developed as in the true myelocyte; (*b*) premyelocytic cells which resemble the non-granular premyelocytes; and (*c*) plasmacytic, on account of their resemblance to plasma cells. Type B appears to be distinguished from C by the failure to stain characteristically with polychrome blue or pyronin-methyl-green, by the appearance of the nucleus, especially the absence of a mural arrangement of the chromatin, and sometimes by the larger size of the cells.[8 9] It is noteworthy that Permin's[10] three

FIG. 6.



Section of myeloma, Case 2, × 1200. Cells also of plasmacytic type. In addition to ragged cytoplasm note—*a*, eccentric nucleus; *b*, wheel-shaped nuclei; *c*, nucleolus; and *d*, vacuole in cytoplasm.

cases are all described by him as being of the premyelocytic type, while Christian described his six cases as being all of the plasmacytic type. This suggests that further research will show that the differences in the type of cell are more apparent than real, and are the result of differences in fixation, staining, and description, or perhaps in degree of anaplasia. The question is further complicated by the fact that the exact microscopical characters of the plasma cell are keenly disputed, while their occurrence in normal bone marrow is not universally recognised.

The unusual nature of the proteins found in the urine, though due in all probability to a more complete investigation in their chemical structure, might suggest that our case was an anomalous one. But the histological examination demonstrates conclusively that it is not only a true myeloma, but is practically identical with the cases classified by Christian, Wright,[11] and Ledingham as the plasmacytic type of growth. It appears to be the eighth example of this form of myelomatous tumour.

Addendum.

Cases of multiple myeloma are so rare that reference may be made to one which occurred in 1903.

CASE 2.—The patient, a male aged 49 years, under the care of Sir James Barr, died after six months' illness with numerous tumours in the vertebræ and ribs, while Bence Jones proteid was constantly present in the urine. The case was published by Moffat[12] in 1905 (who stated that the majority of the cells "were of the lymphocyte type"). Fortunately, one stained section is available, also a piece of growth preserved in Müller's fluid, and originally fixed in formol; from this paraffin sections were cut. The microscopical appearances of the tumour (Fig. 6) were identical with those of the preceding case, except that in the sections prepared from the tissue kept in Müller's fluid the nuclei were on the average 1μ larger, and as the peripheral distribution of the chromatin was more marked so the wheel-shaped appearance of the nucleus was more definite. The vacuolation of the cytoplasm was rather less distinct, though perinuclear halos were found. The other point of difference was the complete failure to stain the cells in a characteristic manner with pyronin and methyl-green even after oxidation with permanganate of potash, a failure which is almost certainly due to the method of fixation and the age of the specimen. The evidence therefore shows that this tumour is also of the plasmacytic type.

A RADICAL OPERATION FOR MALIGNANT DISEASE OF THE TESTIS.

BY RUSSELL HOWARD, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, LONDON HOSPITAL; SURGEON, POPLAR HOSPITAL, ETC.

THE question of a radical operation for malignant disease of the testis has come more and more to the front of recent years. In other parts of the body the operations for malignant disease have been progressively elaborated until it is an axiom that extirpation of the growth, with the lymphatic glands the part drains into and the intervening lymphatics is the only radical form of operation, and that this should be done in all cases. In the case of the testicle, however, the deep situation of the involved lymphatics and the important structures which lie near them have appeared to negative the usual operative procedure, and surgeons on the whole have been content to perform castration and to trust that the lymphatics are not already infiltrated. The very few cases that escape subsequent recurrence in the glands show on what feeble grounds this hope rests, and a radical glandular operation appears to be the more urgent as local recurrence in the scrotum is rare.

Dr. J. B. Roberts of Philadelphia, in a paper published in 1902,[1] pointed this out, and he described a case in which he attempted to remove the glands by a transperitoneal incision. The operation, however, ended in the death of the patient after some months of illness. Dr. W. Osler, in a clinical lecture on Abdominal Tumours Associated with Disease of the Testicle, commented on this case as follows: "It would seem reasonable in all cases to remove them [the glands] as well as the primary tumour."[2] In a paper on the Clinical Aspects of Malignant Disease of the Testis published in 1907,[3] after analysing 57 cases and finding an overwhelming number with metastases in the glands, I discussed the possibility of more radical treatment, and argued that Dr. Roberts's case had shown that this was anatomically possible.

In THE LANCET in 1909[4] Mr. J. Bland-Sutton published a case of an improved method of removing the testicle and

spermatic cord for malignant disease, in which by an extra-peritoneal operation he had removed malignant glands from the lumbar region in a patient with malignant disease of the right testis. At the same time he removed the diseased organ with the spermatic cord and its lymphatics. Commenting on this case in an admirable paper on the lymphatics of the testicles recently published in THE LANCET (Fig. 1),[5] Dr. J. Kay Jamieson and Mr. J. F. Dobson say: "It cannot be allowed that either the operation of Dr. Roberts or that of Mr. Bland-Sutton warrant the use of the term 'radical'; by neither method is the 'lymphatic area' removed." They point out that "careful search," mentioned by Mr. Bland-Sutton, for the lymphatic glands is not the modern principle of dealing with malignant glands, "but the removal of masses of tissue known to contain glands, without any reference to individual glands," and that "the only effective way of securing them is to extirpate the cellulo-fatty tissue from a given area in which the glands are known to lie."

FIG. 1.

Arrangement of lymphatics of left testicle after Jamieson and Dobson.

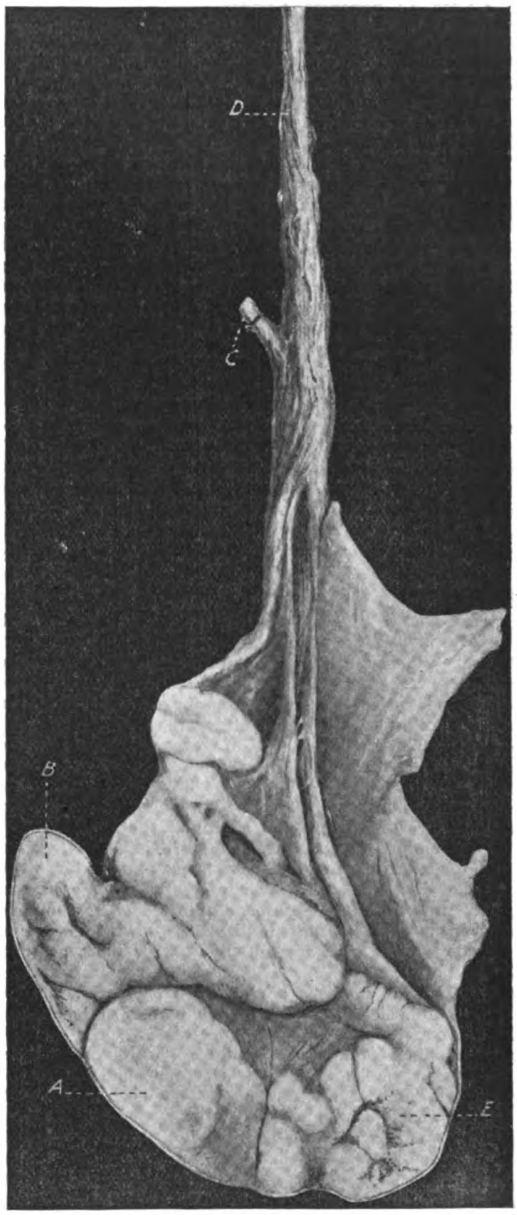
Since writing in 1907 I have been awaiting an opportunity for a radical operation on malignant disease of the testis, and this opportunity arrived in July, 1910, after the publication of Mr. Bland-Sutton's and Dr. Jamieson and Mr. Dobson's papers.

Notes of case.—The patient, a boy, aged 10 years, was admitted into the London Hospital complaining of a painless swelling of the left testis which had been present for ten weeks and which was increasing in size. On examination the left side of the scrotum was occupied by a soft irregular mass in which it was impossible to distinguish the body of the testis from the epididymis. A small hydrocele was present; the vas and cord were not involved. Rectal examination revealed nothing abnormal, and a careful examination of the abdomen revealed no mass in the lumbar region. The case was diagnosed as malignant disease of the testis, and a radical operation was decided upon.

Experiments carried out on the cadaver showed that it was possible to expose the aorta thoroughly by an extra-peritoneal incision, and notwithstanding the opinion of Jamieson and Dobson that "the transperitoneal method appears to be preferable," an extra-peritoneal operation was decided upon, as in Mr. Bland-Sutton's case. The object of the operation was to do a thorough radical operation on the lymphatic area into which the testis drained on the modern principles of the treatment of malignant growth, and that in spite of its being on the left side, and though Jamieson and Dobson say "that the intimate relations of the glands to the inferior mesenteric vessels and the renal vessels, and the fact that many of them lie under the duodenum, appear to forbid even a partial operation." At the same time it was fully recognised, according to Jamieson and Dobson's statement, that "the only effective method of removing the lumbar glands would be to strip the aorta and vena cava, the common iliac vessels, the upper part of the spermatic vessels on either side, and the trunk of the inferior mesenteric artery, of all the cellulo-fatty tissue lying around and between them from the level of the renal arteries downwards."

The operation.—An incision was made into the testis so as to confirm the diagnosis. This was found to be correct, and an incision was then made over the external ring and the spermatic cord was separated and ligatured so as to avoid loss of blood from the incision into the testis. A second incision was then made from the external ring in a curved direction external to the linea semilunaris to about 1½ inches above the umbilicus. All the layers of the abdominal wall were cut through and the peritoneum was exposed. This was dragged away from the retro-peritoneal tissue and was found to strip readily; the stripping was continued until the aorta and the common iliac and external iliac arteries were thoroughly exposed from the renal vessels downwards, the peritoneum being held back with broad retractors. The exposure was very thorough, and the whole length of the vessels was easily seen by the onlookers. The tissue round the aorta, renal arteries, inferior mesenteric, common and external iliacs, and the commencement of the internal iliacs was removed with scissors and Kocher's dissector until the vessels were quite clean as in an ordinary dissecting-room dissection. Numerous glands were removed in the tissue, but none seemed to be enlarged. When the big vessels were quite clean attention was turned to the spermatic vessels, which, with the lymphatics, had been turned back with the peritoneum. The testis with part of the scrotum was detached from everything except the spermatic

FIG. 2.



The parts removed. A, Body of testis. B, Globus major. C, Vas deferens. D, Artery, veins, and lymphatics removed in one piece. E, Globus minor.

cord, and the vas was ligatured as it turned down into the pelvis. The spermatic vessels were then stripped away from the peritoneum as far as the renal vein, a ligature was applied, and the whole growth, artery, veins, and lymphatics were removed. (Fig. 2.) The exposure of the vessels, &c., was so complete that the dissection was easily carried out without

[5] Jamieson and Dobson: THE LANCET, Feb. 19th, 1910, p. 493.

any danger. The duodenum readily turned back off the aorta. After removal of the testis the peritoneum was replaced, the retro-peritoneal area was drained with a tube, and the abdominal wall was sutured. The whole operation took one hour; there was no marked shock, and bleeding was insignificant.

The patient's convalescence was interrupted by a mild attack of pneumonia, but he left the hospital three and a half weeks after the operation with the wound soundly healed.

Dr. H. M. Turnbull, of the London Hospital Pathological Institute, reported as follows: "Small round-celled sarcoma of the epididymis and testicle. The growth consists of closely packed rounded cells with dark nuclei and very little protoplasm. The globus minor shows almost perfectly homogeneous infiltration with sarcoma cells. The left iliac glands and the left lumbar glands are normal, and show no sarcoma cells." The growth is peculiar in that it appears to have primarily affected the epididymis and to have spread to the testis, and not to be a primarily malignant growth of the body, as is usual.

The case was perhaps a fortunate one as a first operation in that it occurred in a thin boy, but that a truly radical operation on the lymphatic area in malignant disease of the testis is possible cannot be disputed. In fact, the operation went a step further than Jamieson and Dobson's ideal operation, in that it cleared the whole of the external iliac artery and vein, instead of the upper third only, and their dictum that the operation "is exceedingly difficult and dangerous, if not impracticable," does not hold good in boys, at any rate.

Devonshire-street, W.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY INTRAVENOUS INJECTIONS OF CHINOSOL WITH FORMALDEHYDE.

BY JOHN McELROY, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

WHEN so much publicity is being given to the prevention and treatment of tuberculous conditions, the history of what seemingly is a rapid and perhaps permanent cure of a pulmonary tuberculous case may be of interest to readers of THE LANCET. Some of my professional brethren more fortunately situated as regards cases for extended trial of the treatment might see if their results were as pronounced.

Last year, when in Bootle, Liverpool, the intravenous injection of formaldehyde in pulmonary tuberculosis was brought to my notice by Dr. F. W. Baker Young, who used the apparatus as recommended by Dr. Robert Maguire of the Brompton Chest Hospital, but modified the strength of his solutions, and used as a medium sterilised distilled water instead of saline solution. I have heard and read of various germicides being used intravenously, but so far have not heard of anyone using chinosol, a quinine potash compound, and a very powerful germicide. In the following cases I used it in conjunction with formaldehyde with most gratifying results.

CASE 1.—The patient, a man aged 54 years, had been ailing for almost 12 months with a history of hæmoptysis, pleurisy, cough, and profuse expectoration, and of having lost a considerable amount of weight. Acting on the advice of his medical attendants he spent four months at a sanatorium, and, although he put on 21 pounds in weight, when he left he was in a very weak condition, and the cough and expectoration had decreased very little. He tried as well as possible when at home to keep up his sanatorium methods, and for five weeks held his own as far as his weight was concerned, but was not getting any stronger. He then began to lose weight, and for the three weeks before coming under my care lost 1 pound, 1½ pounds, and 2½ pounds respectively. Under the intravenous injection of chinosol and formaldehyde he recovered his weight, rapidly regained strength, and at the end of four weeks' treatment was able to walk—without unduly distressing himself—two or three miles at a time. His chest condition before treatment showed symptoms of a cavity at the apex of the right lung, with signs of involvement of the middle and lower lobes. After treatment all adventitious sounds had disappeared, and the only appreciable deficiency was at the apex, where the expansion was not what it ought to be, this naturally being due to the contraction brought about by the healing process. Dr. J. A. Sinton of the Queen's University, Belfast, examined the sputum for me before, during, and after treatment, and reported as follows:

Before treatment.—Oct. 23rd, 1909: Tubercle bacilli very numerous and averaging about 15 per field.
During treatment.—Nov. 1st: Tubercle bacilli less numerous. 23rd: Tubercle bacilli scanty. Dec. 13th: Tubercle bacilli very scanty and nearly all of the granular type, and averaging about one per field.
Since treatment.—Feb. 21st, 1910: Tubercle bacilli absent. April 18th: Tubercle bacilli absent.

From Dec. 13th, 1909, onwards I was unable to get a specimen of sputum, but on Feb. 21st, 1910, the patient was working all day in the rain and dried his wet clothes on himself. He then took an acute attack of bronchitis, and at this time I had his sputum examined, when Dr. Sinton, after a most exhaustive examination, was unable to detect any tubercle bacilli. I was able to get a small specimen again on April 18th, and Dr. Sinton notified me that he was still unable to detect any bacilli. At the present time (Nov. 5th) the patient is as well as possible and is working as hard as ever he did in all kinds of weather. He cycles to and from his business, distant over two miles, and all uphill the one way. Expectoration is completely absent. The patient is an engineer, commences his work at 6 A.M., and is often working all night.

Since treating the foregoing case I have had two more cases under my care, brief details of which I will now give.

CASE 2.—In this case expectoration has been reduced to less than one-half, the weight has increased to normal, and the patient's strength has improved vastly. The sputum at the present date shows a reduction in tubercle bacilli from 20 to 12 per field, and the granular type is now predominant. This patient at first only got half the number of injections I considered he would require, as he developed a phlebitis in his veins and I had to stop treatment. He is again receiving injections, but unfortunately I have a great deal of difficulty in administering them, as his veins seem to be very easily irritated. He has, however, not lost ground. His chest condition is much better and the negative lung pressure is almost doubled.

CASE 3.—This patient is still under observation, but I have stopped treatment, and he has been working at his trade—that of a ship carpenter—for the last five weeks. The night sweats stopped after about ten injections and his temperature became normal, fluctuating occasionally until Sept. 13th, when it became normal, and has since continued to do so. I administered the first injection upon July 6th, and between that date and Sept. 18th administered 36 injections in all. On Oct. 3rd he resumed work, and at the present date he is working hard from 6 A.M. till 5.30 P.M. in all kinds of weather without experiencing any ill results. He can walk five miles in one and a quarter hours without undue fatigue. All râles and crepitations have disappeared from the chest, medium râles being very pronounced back and front in right lung and fine crepitations in upper portion of left lung before treatment. Expectoration is almost absent, the tubercle bacilli being reduced from 40 to 8 per field, the bigger number in this case also being granular. At the same rate of decrease I hope to see it negative in about another two months.

The method of administering injections was as follows, Dr. Maguire's apparatus being used. 50 cubic centimetres of a 1/2000 solution of formaldehyde plus 1/4000 solution of chinosol were injected into the median-basilic or median-cephalic vein—the usual precautions being taken—and this was repeated daily, the strength being gradually increased.

In Case 1 I administered 33 injections altogether on 33 consecutive days, the strength being increased to 1/500 in the case of the formaldehyde and to 1/1000 in the case of the chinosol. Many cases will require more injections, but I do not consider it advisable to increase the strength of the formaldehyde above 1/500, the strength of the solution being increased above that figure by increasing the chinosol from 1/1000 to 1/500. Beyond slight gastric disturbance the patient suffered no inconvenience.

Has the chinosol in conjunction with the formaldehyde, when injected intravenously, any destructive effect upon the tubercle bacillus itself; or, on the other hand, does it assist nature's efforts and cause a reactive inflammation around the tuberculous area, and so encapsulate the caseous mass, and by so doing not only isolate and bring about the natural cure of the diseased area, but prevent the admission of the

ordinary bacteria of suppuration which are an additional danger to the natural process of healing? If quinine has a specific action on the malarial fevers, is it not possible that in the case of chinosol, injected intravenously, it may have a selective, destructive action upon the tubercle bacillus itself? In Dr. Sinton's report of Dec. 13th on the sputum of the patient in Case 1, the bacilli were practically all of the granular type, and in the reports of the sputa in Cases 2 and 3 the bacilli have become more granular. This condition I consider is worthy of further inquiry, and suggests direct action upon the bacilli.

Sanatorium treatment is undoubtedly of great assistance in retarding the progress of the disease, but I have yet to meet with a case with pronounced chest symptoms and a sputum rich in tubercle bacilli that sanatorium treatment alone has so definitely or so quickly arrested. I have seen the reports of several sanatoriums and in none have I seen any record made of the sputum conditions when the patient left the sanatorium. What is the good of a treatment if the patient—even if a good deal improved—is allowed to expectorate promiscuously a sputum containing tubercle bacilli? This is where the real danger lies. Until we have more stringent laws relative to the proper preventive measures to be adopted against infection, sanatorium treatment alone will not be of as much service to the community as it might.

There are other points which one might elaborate at great length, more particularly the proper segregation of patients in sanatoriums, but what I have written is primarily to call attention to the possible, I think I might say probable, efficacy of intravenous injections of chinosol and formaldehyde.

I have to thank Professor J. A. Lindsay for kindly examining the first of my three patients after treatment; Dr. Sinton for his most careful examinations of the sputum; and Dr. Baker Young for his practical instructions in the technique of intravenous injections.

Belfast.

NOTES ON THE OPERATIVE TREATMENT OF PAPILLOMA OF THE BLADDER.

BY J. W. THOMSON WALKER, M.B. EDIN., F.R.C.S. ENG.,

ASSISTANT SURGEON TO ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES.

THE recurrence of papilloma of the bladder after operation is a commonplace of surgical conversation and a constant, if reluctant, admission of all writings on the subject. Our present knowledge would lead us to suppose that there may be several factors involved in the causation of this recurrence. I shall here deal only with those which are specially related to the technique of the operations undertaken for the removal of these papillomata. Two probable and important causes of recurrence are: (1) the incomplete removal of the papilloma at the time of the operation; and (2) the implantation of fresh papillomata during the operation. In the course of cystoscopic examinations upon patients previously operated upon for papilloma of the bladder by other surgeons at a recent date—that is to say, within a few weeks or months of the operation—I have in more than one case noted a small bud of papilloma or two small buds present in the bladder. On more detailed examination I found that the papillomata were set at the edge of the scar which resulted from the removal of the original growth. The following notes are illustrative of this statement:—

CASE 1.—The patient was a man, aged 35 years, who came under my observation at St. Peter's Hospital in August, 1908, suffering from hæmaturia. Two months previously he had undergone an operation for papilloma of the bladder at the hands of another surgeon. On cystoscopy the bladder was healthy, with the exception of an area in the neighbourhood of the left ureteric orifice. (Fig. 1.) A quarter of an inch outside the left ureteric orifice there were two small buds of papillomatous growth close together, and rather less than a split-pea in size. From the base of these, folds of unusually smooth and firm-looking mucous membrane passed inwards towards the middle line. In this scar tissue the left ureteric orifice appeared as a slit running parallel to the folds. I obtained the following information in regard to the operation. At the end of May, 1908, a fairly large pedunculated papilloma was found to the outer side of the left ureteric orifice and a smaller one lying near the apex of the bladder. The large growth was grasped in forceps and twisted off. Another small growth was similarly treated. Oozing from the base of each was stopped by touching with the electric cautery. In December, 1900, eight years previous to this operation, he had undergone a similar operation for a pedunculated papilloma situated outside the left ureteric orifice. In this case, therefore, there was recurrence in the same spot

FIG. 1.

Cystoscopic view of recurrent papillomata on scar of previous operation. The ureteric orifice is seen in the scar.

after two similar operations. In such cases the operation, whatever form it took, was not sufficiently radical to remove the whole growth.

Yet another form of recurrence may be met with after the removal of a papilloma. At some part of the bladder adjacent to, or remote from, the site of the original growth one or more papillomata are found, while the operation area is free from growth. I have no doubt, from the size of the papillomata and their discovery so soon after the operation, that in some of these cases the tumours were present when the original papilloma was removed, but were overlooked.

There are other cases where a solitary papilloma has been carefully localised and its isolation definitely determined by a pre-operative cystoscopy, and where, in about a year later, the bladder has been found strewn with numerous sma papillomata.

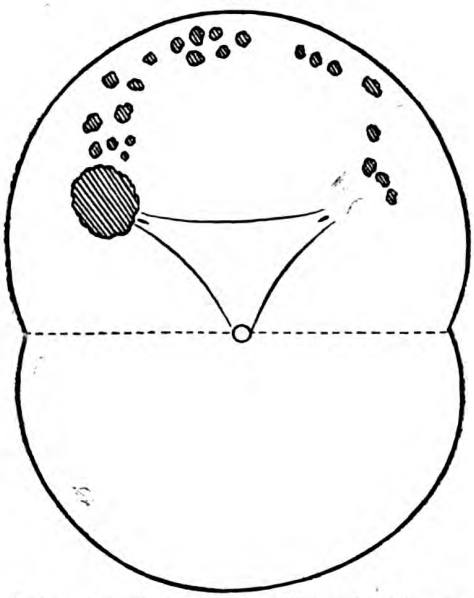
CASE 2.—In August, 1905, I removed a pedunculated papilloma from the neighbourhood of the right ureter in a man aged 31 years, who had suffered for 12 months from intermittent hæmaturia. The operation was performed by placing a clamp on the pedicle of the tumour and clipping away the papilloma with curved scissors. The clamp was removed and the electric cautery applied to the base to stop oozing. Three months later a few drops of blood were noticed at the end of micturition. In February, 1906, attacks of hæmaturia commenced and recurred at intervals until I saw him in August, 1906. The hæmaturia lasted four or five days and the blood was well mixed with the urine. There was increased frequency of micturition to 12 or 14 times and scalding during the act. Cystoscopy in June, 1906, showed a fair-sized papilloma on the outer lip of the right ureter at the spot from which the first tumour had been removed. From this spot there was a track of tiny papillomatous buds, which passed in the form of an arc to the apex of the bladder and continued symmetrically across the other side of the bladder almost to the left ureter. The number of these small papillomata was between 20 and 30. (Fig. 2.) In such a case it seems most probable that the small papillomata are seedlings implanted on the bladder wall at the time of the operation, and the trail that they frequently form from the site of the original growth to the scar of the cystotomy wound is evidence in support of this view.

In operating upon cases of recurrent papilloma I have frequently found the largest growth situated on the site of the scar of the cystotomy wound or immediately adjacent to it. There may or may not be a recurrence at the site of the original growth. I have little doubt that such a papilloma was implanted during the removal of the original growth. The two cystoscopic charts, which follow, are selected from a number of such cases. They are reproduced from patients

on whom I afterwards operated. The following is a brief synopsis of these cases:—

CASE 3.—The patient, a married woman, aged 56 years, was under the care of Dr. T. Hoskings, who asked me to see her for severe hæmaturia in October, 1909. Six years previously a small papilloma had been removed by another surgeon after six months of intermittent hæmaturia. She

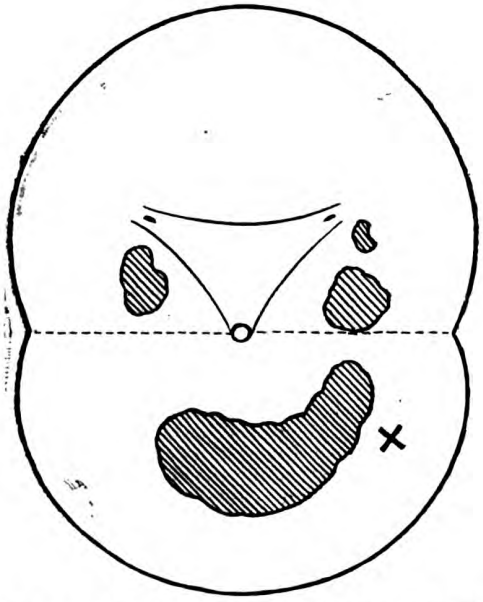
FIG. 2.



Cystoscopic chart of recurrent papillomata forming an arc extending to apex of bladder.

was free from symptoms for 18 months, and then the bleeding recommenced, and had continued at intervals since. The intervals between the attacks varied from one to six weeks. I saw her during a period of hæmaturia, which had been continuous for 14 days. The urine was dark brown and con-

FIG. 3.

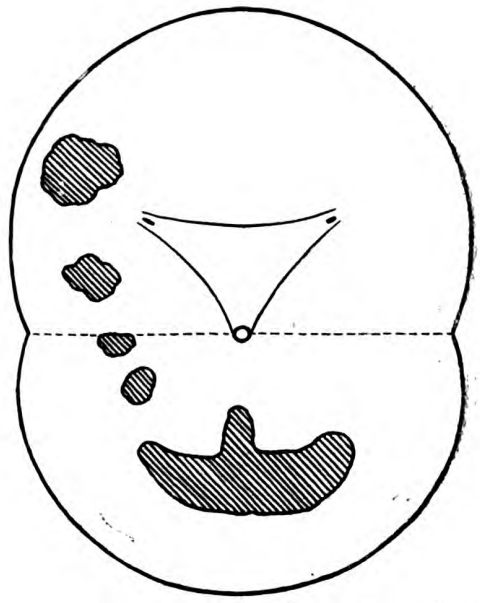


Cystoscopic chart of recurrent papillomata. The largest mass lay on the old cystotomy scar. At × a small bud of papilloma was hidden from view and discovered at operation.

tained clots. The patient was a stout, healthy looking woman. Cystoscopy showed four distinct papillomatous growths, three of which were of medium size and subsessile, varying from the size of a large pea to that of a hazel-nut, while the fourth was a large mass about two and a half inches in breadth and lying across the middle line on the anterior wall about half-way between the urethral meatus and the apex. (Fig. 3.) The surface of the growths was sponge-like without any long tentacles. There was no sign of infiltration of the mucous membrane of the bladder. The mucous membrane around the right ureteric orifice was scarred and the papilloma had probably been removed from this spot. I excised the papillomata in the manner that I shall presently describe.

CASE 4.—The second chart (Fig. 4) represents the bladder in the following case. The patient, a man aged 34 years, had a severe attack of hæmaturia with some pain in the right lumbar region. In August, 1907, he was admitted to a general hospital and confined to bed for three weeks. The blood gradually disappeared from the urine, and he was dismissed as "cured." When he recommenced work the blood reappeared in his urine. I saw him at St. Peter's Hospital in January, 1908, and on cystoscopy found a papilloma close to the outer side of the right ureteric orifice. The rest of the bladder was healthy. The patient was admitted to the

FIG. 4.



Cystoscopic chart of recurrent papillomata. There is local recurrence outside the right ureteric orifice and a trail to the cystotomy wound, on the scar of which the largest mass is situated.

hospital and an operation was performed by one of my colleagues. The growth was grasped in forceps and twisted off "fairly cleanly." The patient was well for 15 months, when the bleeding commenced again. I cystoscoped him in October, 1909, and found five distinct masses of papilloma. One rather low, and apparently sessile, mass lay immediately outside and behind the right ureter in the position of the original growth. These smaller clumps formed an almost continuous track, which passed forwards and upwards to the right of the trigone. On the anterior wall, about two inches above the internal meatus, lay a large mass of papilloma with a long axis of over two inches lying transversely across the middle line. (Fig. 4.) I removed these growths in November, 1909.

It is worth while from the operative point of view to note these points, and so to plan the operation as to avoid such sources of recurrence. For some years past I have operated with this view, and the following is an account of the technique that has developed.

1. *Preliminary cystoscopy.*—Apart from the question of diagnosis of a bladder growth and of the recognition of its nature, a pre-operative cystoscopy should be made to determine the exact number and position of the papillomata. It is not sufficient to trust to touch and sight to display the number and position of the growths *after* the bladder has

been opened. The bladder is a deep-seated collapsible organ, which falls into innumerable folds when it is opened. Among these folds papillomata are readily concealed. The surgeon who trusts to cystotomy to display the tumours is likely to overlook small buds or even papillomata of some size which are hidden between these folds. This is more likely to happen where cystitis is present as a complication. After the removal of one papilloma bleeding frequently obscures the view, so that unless there is some previous knowledge as to the exact number and position of the growths the surgeon is working at a disadvantage.

Where the papillomata are multiple I make a chart of their number and position, and with this before me at the operation there is little likelihood that small detached papillomata will be overlooked. Two of these charts have been reproduced to illustrate the cases just described. With the bladder fully distended with fluid and a good light the growths are readily counted and localised with the cystoscope.

Two difficulties in regard to this pre-operative cystoscopy may be mentioned. Occasionally on the anterior or lateral walls a large papilloma may conceal one or two smaller buds from view when they lie immediately behind (Fig. 3, ×), but in this position they are little likely to escape observation at the operation, and it should be the first care of the surgeon on opening the bladder to verify the numbers and position of the tumours already charted, and to note any that may be hidden from the cystoscopic view. Again, the mere size of a single papilloma may so fill the bladder that the beak of the cystoscope sinks directly into its folds. Complete darkness may be the result, or the folds of the growth restrict the movements of the cystoscope beak and only permit a small part of the growth to be seen. Such a case as the following is, however, rare.

CASE 5.—In September, 1909, I saw a man, aged 58 years, in consultation with Mr. J. F. Jennings. He gave a history of 12 months' hæmaturia, which first appeared after bicycling. There had been three attacks of hæmaturia of sudden onset and short duration. Cystoscopy was performed under eucaine. The bladder wash returned clear at once, and a distension of 10 ounces was borne without discomfort. On introducing the cystoscope the bladder appeared to be very dark, and there was a little difficulty in manipulating the cystoscope. On rotating the instrument the edge of a papilloma, close to the window of the cystoscope, suddenly became brilliantly illuminated, and I realised that I had pushed the beak into the middle of a large papilloma. Subsequent efforts to obtain a better view were fruitless, and operation was recommended. On Sept. 7th I removed a large single papilloma the size of a Tangerine orange. The rest of the bladder was healthy.

2. *The proper exposure of the growth.*—A vertical median suprapubic wound of 3 inches will suffice for most operations upon vesical papillomata. In stout patients the length of the wound through the skin and fat may be extended, but the separation of the recti need not exceed this limit. An extension of the abdominal wound upwards towards the umbilicus does not give a better exposure of the bladder, but merely uncovers more peritoneum. If further room is required in a powerful man, whose boisterous respiration and the rigidity of whose recti are not controlled by deep anæsthesia, it is best obtained by incising each rectus muscle about 2 inches above the pubes, or if the manipulation is likely to be required on one side more than the other the corresponding rectus may be cut transversely for one-third or so of its width. I usually place a catgut suture through the upper cut end of the muscle at once to help in the repair of the muscle at the completion of the operation. I have not had to resort to a transverse suprapubic incision for the removal of simple papillomata.

When the bladder is opened suprapubically the walls collapse upon the base, so that the whole organ drops down into the pelvis. If the intra-peritoneal tension is low, as it may be in aged and feeble subjects, a large air-filled space is left. Usually, however, the intra-peritoneal pressure forces the peritoneum with coils of small intestine into this space, and the bladder disappears from view. If the edges of the bladder wound are held up by forceps or sutures the posterior wall is forced towards the pubes and the lateral walls towards the middle line by the same pressure, so that a view of the base of the organ cannot be obtained. These difficulties are overcome in the following manner. Having opened the bladder a suture is placed through the whole thickness of each lip of the bladder wound. The patient is now placed in the full Trendelenburg position. This is an indispensable factor in the proper exposure of the interior of the bladder. The bulging of the upper or posterior wall of the bladder now disappears or is easily controlled. There is still a tendency for the lateral walls of the bladder to collapse and hide the base and the abdominal and vesical wounds must be retracted. In order to overcome these obstacles to a full view I have designed a retractor which was recently described in THE LANCET (March 5th, 1910).

FIG. 5.

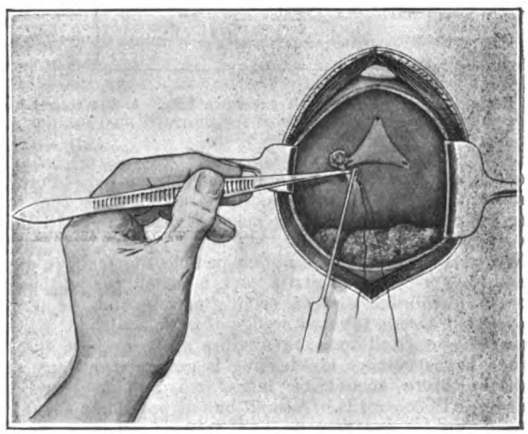
A bladder retractor.

By grasping the handle of this retractor with the thumb held vertically and tucked into the recurved portion, traction is exerted on the abdominal wound, and at the same time the bladder wall is pushed outwards. The shank of the instrument should be flat on the skin of the abdomen. I usually place a broad retractor on the side opposite to that on which the papilloma is set and a narrow blade retractor on the same side. By these means and by the aid of a head-lamp the interior of the bladder is fully displayed.

It is sometimes necessary to place a roll of gauze in the post-trigonal space to control still further a bulging posterior wall. I have found that careful preparation of the bowel beforehand and the quiet anæsthesia of chloroform during the operation are factors which are of some importance. The first care of the surgeon will be to enumerate the growths and compare them with his chart.

3. *The removal of the papillomata.*—Papillomata vary greatly in their relation to the vesical mucous membrane. There are papillomata, invariably single, which are attached to the mucous membrane by a long stalk, and there are others set on a short, thick stem, but still distinctly pedunculated.

FIG. 6.



Removal of a solitary pedunculated papilloma; a thread of catgut is being passed through the base.

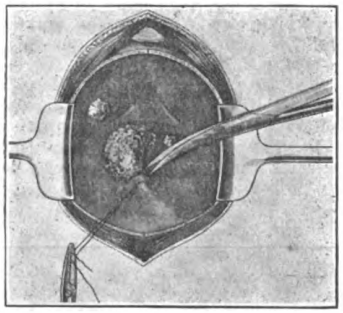
The most frequent type is set upon the mucous membrane like a well-shaped sponge of rather coarse texture, and attached by a base so short that it cannot be called a pedicle, yet too narrow for the arrangement to be termed sessile. There are others which are sessile and which carpet the mucous membrane for considerable areas like a luxuriant

low shrub. All varieties, with the exception of the long pedicled type, may co-exist in the same bladder. A very large growth is frequently solitary, and may have a short and comparatively narrow base of attachment, which may, however, extend along the mucous membrane for an inch or more.

In removing the pedicled variety I usually pick the growth up in long fine forceps, and pass a double strand of very fine catgut through the base of the pedicle, or, better, through the adjacent mucous membrane, which is raised by putting the pedicle on the stretch. (Fig. 6.) A fine, rounded, curved needle is used for this purpose, and held in a long, fine needle holder. For transfixing the base at difficult angles I use a small, fine, curved needle, set at right angles to a long fine handle, which is left untempered for two inches close to the needle, so that it may be bent at will to any angle. The thread of catgut is severed and the needle withdrawn. The two threads are now tied, so that one half of the pedicle is grasped in each, and the pedicle cut through above this. Usually there is no bleeding, but if oozing does occur another stitch may be introduced. The catgut stitches are cut short.

In larger growths with a short narrow base attached along a line of mucous membrane I commence by placing a catgut stitch through the mucous membrane and muscle above the nearest end of the pedicle. This raises a ridge of mucous membrane, and with scissors this is cut across just short of the pedicle. (Fig. 7.) Another catgut stitch is introduced by means of the special needle described above. This is tied and a further cut made with the scissors, taking care to clear the last suture and not to cut it away. Should a vessel spout it is picked up in long pressure forceps, which are left on until the papilloma is removed and then taken off, or a catgut ligature may be applied. Bleeding from these vessels is usually controlled by pressure forceps and the pressure of the sutures which close the wound. The cutting and stitching

FIG. 7.



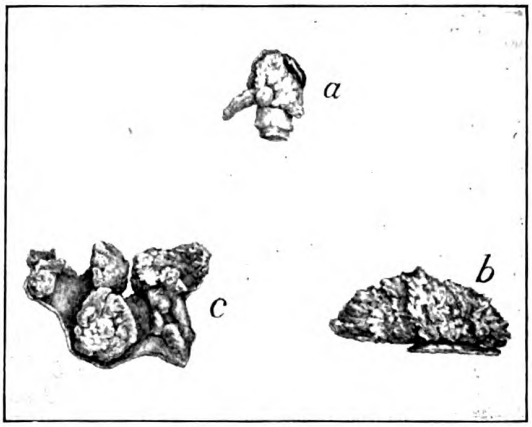
Removal of papilloma with extensive base. A fine catgut suture has been introduced above the papilloma, and the ridge thus raised has been cut across.

are continued until the papilloma is removed. Forcible traction upon the sutures should be avoided, for they will tear out, but gentle traction may be exerted and will bring the wound into closer view.

Where there is a thick, fibrous pedicle the mucous membrane may be cut round its base, a stitch passed through mucous membrane and underlying muscle, and the fibrous pedicle cut across, taking a wedge of muscle with it. Having removed the papilloma the stitches are cut short and the wound is inspected. If bleeding is going on at any spot another suture should be introduced and tied and the pressure will control it. A small bud of papilloma should be picked up in fine forceps and snipped off with curved scissors, taking a piece of mucous membrane with it. The cut edges are then brought together with a fine catgut stitch. Where an area of mucous membrane is carpeted with low, shrub-like growth, the strip of the membrane bearing the growths should be excised with curved scissors, and the cut edges united with a series of fine catgut stitches (Fig. 8). In removing the papillomata care should be taken that the edges of the cystotomy wound are not soiled. Before leaving each little wound the bleeding must be completely stopped. Sometimes an oozing from the mucous membrane is difficult to control, and occasionally a few touches with a fine electrocautery point are necessary.

It will be noted that the above methods are dependent on good exposure, clean cutting, and accurate suture. In my view rapid healing is more likely to be promoted in this way than by any method of crushing, tearing, or twisting of the base of the growth. The catgut sutures have not caused any inconvenience in my hands. On examination of the bladder

FIG. 8.



Three types of papillomata after removal. (*a*) Cauliflower-like papilloma with fibrous pedicle. The mucous membrane has partly retracted from the fibrous core of the pedicle. (*b*) Sponge-like papilloma removed with mucous membrane at base. (*c*) Strip of mucous membrane covered with low shrub-like growth.

with the cystoscope after recovery from such an operation, no trace of the suture is to be found. Silk sutures are to be avoided, as they almost always accumulate phosphate deposit, and give rise to trouble afterwards.

A word must be said in regard to clamps. Some years ago I had a clamp made with flat blades, one grooved and the other ridged, about one-eighth of an inch thick, and set at an angle to strong handles. With this I proposed to clamp the base of the growths, and with an instrument like a large adenoid curette to scrape the papillomata from the surface of the clamp. I found there were several objections to this method. It was very difficult to get clamps of the size and angle to suit the varieties and different positions at which papillomata are found in the bladder, so that if the papillomata were to be accurately clamped a number of instruments would be required. Many papillomata are closely related to the ureteric openings, and there is a very real danger of including the ureteric orifice in the clamp, if the clamp is applied, as it should be, so as to include mucous membrane in the bite. I found further that there was a tendency of some part of a large base to slip out of a clamp altogether, and troublesome bleeding followed.

Where I have to deal with a large solitary papilloma I sometimes use a Guyon's clamp in order to steady the base of the tumour during the stitching. This clamp has a very convenient curve, and on the contact surface of one blade there are several teeth, which sink into corresponding holes on the contact surface of the other blade. This prevents any portion of the pedicle from slipping out of the clamp. The clamp should be carefully adjusted so as to grasp the base of the papilloma with some mucous membrane. When it is in position and locked catgut sutures should be placed on the bladder side of the base, dipping below the convex border of the clamp and out at the other side. These are held aside; the papilloma is clipped away from the concave border of the clamp, which is then removed, and the sutures tied in series, introducing an additional one or more if necessary. This method may be used in the large isolated type of papilloma. It is described and recommended by Albarran.[1] It is not suited to the form in which there are numerous small, scattered papillomata, or where a considerable area of bladder wall is covered with clusters of papillomata.

[1] Médecine Opératoire des Voies Urinaires, 1909.

In operating upon tumours in the bladder, I have frequently noticed a peculiar condition of the bladder wall, and which seems worthy of mention. After working in the bladder for half or three-quarters of an hour the mucous membrane becomes thick and rather œdematous in appearance, and the bladder muscle contracts and thickens, so that the exposure of the interior of the viscus becomes more difficult. These changes are probably due to the prolonged exposure to air, but they are followed by no ill-effects.

Having carefully freed the bladder from blood-clot, and removed gauze pads or swabs from the post-trigonal area, the question of closing or draining the bladder will arise. After a trial of suturing the cystotomy wound in these cases, and after one or two failures from serious hæmorrhage, I have abandoned the method. If the bladder is sutured and the urine, by any chance, such as the blocking of the catheter by a clot or the slipping of the tied-in catheter, accumulates and distends it, hæmorrhage is encouraged, and should hæmorrhage take place a retained catheter, however large, is not a sufficient means of drainage. I now drain the bladder in these cases from the first by means of a large rubber tube, three quarters of an inch in diameter. A stitch or two are usually required to close the bladder wound around this tube. In addition I place a small rubber tube, which dips into the prevesical space, at the lower angle of the wound. This ensures the removal of any urine which may escape into this space. The abdominal wound is carefully repaired by uniting the cut portions of recti and approximating the recti muscles by means of catgut sutures.

In the after-treatment I use a very simple method of removing the urine which is neither a syphon nor a suction method, but merely drains the overflow. One end of a yard of medium-sized soft rubber Paul's colotomy tubing is drawn over the prominent end of the rubber drainage-tube and tied round with a piece of silk to retain it. This is brought through the dressings and passing over the edge of the bed dips into a jar. To ensure that the surfaces do not adhere and block the flow of urine two drachms of olive oil are poured through the tube before adjusting it. The tube is changed at each daily dressing, when the bladder is irrigated with oxycyanide of mercury (1 in 10,000). On the fourth day the drainage-tubes are both removed and the urine may be allowed to soak into large pads of cellulose wadding, or an Irving apparatus may be applied. In my experience the wound heals more quickly without any apparatus.

Queen Anne-street, W.

ON CHRONIC BRONCHITIS AND EMPHYSEMA AS THE RESULT OF ACUTE PNEUMONIA.

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN AND LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, ST. BARTHOLOMEW'S HOSPITAL, ETC.

IT is not surprising that so severe a disease as pneumonia should be followed by serious nutritive changes in the lungs. Of the local changes in the consolidated parts it is not necessary to speak. I wish to draw attention to less recognised results which affect the lungs generally. The two affections I refer to are bronchitis, on the one hand, and emphysema on the other.

The signs of bronchitis associated with pneumonia in its acute stage have a different significance according as they have preceded the attack of pneumonia or developed in the course of it. Where the pneumonia is subsequent—i.e., occurs in the course of bronchitis—the association of the two affections is awkward but not necessarily of very grave significance. Where, on the other hand, the physical signs of general bronchitis develop in the course of the pneumonia they indicate not a mere bronchitis or complication of the pneumonia but pulmonary failure, a very serious condition and almost necessarily fatal.

In a severe case of pneumonia the pathological changes are not limited to the parts which become consolidated but are widespread and affect the whole of both lungs. This is recognised pathologically, but clinically is usually disregarded unless during the acute stage the signs of congestion develop in the rest of the lungs. After the pneumonia is past these general nutritive changes leave behind a delicacy of the lungs which may last for months and show itself in a tendency to bronchitis on slight provocation. If this were recognised and dealt with appropriately the patient might be spared much distress and saved the risk of becoming a chronic bronchitic.

Besides bronchitis, there is also emphysema to be considered. Vicarious or complementary emphysema is, of course, common enough during the acute stage of pneumonia, but this is only transient and rapidly passes away. True or ordinary emphysema may be observed, and not rarely if it be looked for, to develop after pneumonia in a patient who before the attack presented no signs of it, so that I cannot doubt that the nutritive disturbances produced during the acute attack may, and not infrequently do, initiate those atrophic changes which end in the wasting and atrophy of the alveolar walls characteristic of ordinary emphysema.

Much might be done to obviate these risks if it were known and remembered how profoundly the general nutrition of the lungs is affected in any severe case of pneumonia, and that the delicacy thus engendered may lead to recurrent bronchitis and to permanent emphysema.

It should therefore be the rule of practice to take great care of a convalescent from pneumonia for at least 12 months. This rule is often disregarded and with disastrous results, for the reason that the resolution of the local lesion is so rapid and complete that the possibility of any widespread changes such as those to which I have referred is not recognised or suspected.

Wimpole-street, W.

AORTIC REGURGITATION.[1]

BY WALTER BROADBENT, M.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL; PHYSICIAN TO THE ROYAL ALEXANDRA HOSPITAL FOR CHILDREN.

DILATATION and hypertrophy of the heart are carried to a greater extent in aortic regurgitation than in any valvular disease. Heaving pulsation of the lower chest is very evident until the heart is failing seriously. Often there is systolic retraction of the intercostal spaces near the sternum, due to atmospheric pressure and not to adherent pericardium. Also systolic retraction of the lower ribs at the back on the left, and even the right, may be caused by the hypertrophied heart pulling on the diaphragm, which is attached to these ribs. This used to be considered a sign of adherent pericardium, and is so if the heart is not much hypertrophied, but a large heart can pull on the diaphragm sufficiently to cause it without the pericardium being adherent.

At the apex the first sound is prolonged and not as loud as normal. A systolic murmur is often present, which may be conducted from the aortic orifice, or may be that of mitral regurgitation. If the murmur, traced from the aortic cartilage across the chest to the apex, becomes progressively less loud, one may conclude that it is conducted, but if it becomes less loud about half-way and increases towards the apex, it is mitral. Also when it is mitral, the first sound is diminished and may be absent at the apex, and the murmur is conducted outside the apex beat. A second sound is heard and usually a soft diastolic murmur.

Not infrequently a presystolic thrill can be felt and a loud presystolic murmur heard at the apex. Mitral stenosis would be incompatible with life, if there was much aortic regurgitation, blood would never get through a stenosed mitral orifice against the pressure in the left ventricle, and where the pulse is large and collapsing no mitral stenosis is found post mortem. The probable explanation is that the regurgitant stream from the aorta strikes against the anterior flap of the mitral valve and causes vibrations in it, or it may be that the valve is prevented by the aortic regurgitant stream from falling back, and so lies across the mitral orifice to a certain extent. This is sometimes called Flint's murmur, having been first described by Austin Flint in 1862. When there are aortic stenosis and regurgitation, in which the stenosis

[1] Portion of a paper read before the Brighton and Sussex Medico-Chirurgical Society.

predominates, mitral stenosis is not infrequent, but even then a presystolic murmur is not always heard. I remember one case where post mortem there were mitral and tricuspid stenosis as well as aortic stenosis, with some regurgitation, but no presystolic murmur was heard during the two months she was in hospital, but the first sound at the apex was short and loud.

Thayer, at the Johns Hopkins Hospital in 1901, found in 74 cases of aortic regurgitation followed by post-mortem examination 45 had had a presystolic murmur during life, but in only 12 was there any mitral stenosis, and in these the pulse was noted as not large, and in most of them there was a short loud snapping first sound at the apex. But of the 29 with no presystolic murmur 4 had mitral stenosis. He illustrates the difficulty of diagnosis by a percentage table of physical signs, and concludes that the size of the pulse is the most reliable guide.

	Pure mitral stenosis, 17 cases.	Mitral stenosis and aortic regurgitation, 14 cases.	Aortic regurgitation and Flint's murmur, 33 cases.
	Per cent.	Per cent.	Per cent.
Small pulse	82·3	28·5	0
Presystolic thrill ...	64·7	50·0	42·0
Tapping systolic shock	76·4	50·0	15·1
Snapping first sound	64·7	78·5	30·3

The systolic blood pressure, as measured by the sphygmomanometer, is very high in aortic regurgitation, but the diastolic is low. The difference between the systolic and diastolic pressures is a fair measure of the amount of regurgitation, the greater the difference the greater the regurgitation.

The pulse is sometimes bisferiens; a distinct double beat may be felt when moderate pressure is put on the artery. In a tracing there is a double top to the wave, the second being higher than the first. This is often only present on the left side, while the right pulse is normal, and it is, I believe, invariably more marked on the left side. Some aortic stenosis or high peripheral resistance has been present in all the fully described cases. Roy and Adami, in their investigations on the hearts of dogs in 1890, found that a rise of peripheral resistance made the intra-ventricular pressure curve anacrotic, as if the contraction were reinforced by a renewed effort. It is probable, therefore, that in cases of aortic regurgitation with stenosis supervening the intra-ventricular pressure curve would be anacrotic, and, if the valves are much destroyed, the pressure curve in the aorta would correspond closely to the intra-ventricular, and an anacrotic or bisferiens pulse might be conveyed to the arteries. The explanation of the bisferiens pulse being more marked in the left carotid and radial is that the natural direction of the main blood stream is towards the left carotid (a fact often quoted as the cause of the greater frequency of cerebral embolism on the left side), and so the pressure curve of the aorta is more readily conveyed.

To estimate the amount of regurgitation the pulse is the most important factor. A large artery and very collapsing pulse, when the wrist is held above the level of the shoulder, indicate much regurgitation, and *vice versâ*. But if the pulse is irregular proper compensation has not been attained, and there is more regurgitation than the pulse shows. In the last stages there may also not be sufficient force in the heart to produce a collapsing pulse at all. In atheromatous regurgitation the artery is large and tortuous from long-standing high tension, but there is not the same collapse of the pulse; sphygmographic tracings show a more sustained wave, and the amount of regurgitation is never very great.

The degree of dilatation and hypertrophy of the left ventricle is a help in estimating the extent of the regurgitation, but, if prolonged rest has not been insisted upon after the onset or after illnesses attended with fever, the dilatation will be in excess of what was necessary for compensation.

If the heart is much hypertrophied but the pulse is not correspondingly collapsing, either aortic stenosis predominates or the hypertrophy is the result of old high tension or kidney disease. If due to aortic stenosis there will be no second sound heard in the carotids, the pulse wave will be long and slow and the artery soft walled; but if due to old high tension the second sound in the carotids will be loud and the artery thick walled and probably tortuous.

Prognosis.

"When, with a diastolic murmur, the aortic second sound is still audible in the neck, the pulse exhibits the collapsing character only in a moderate degree and the dilatation and hypertrophy of the heart are inconsiderable, the patient may be expected to enjoy life and do hard work for many years, provided the lesion is due to acute endocarditis," and not to syphilis or atheroma. In practically all such favourable cases the onset is before the age of 20.

Atheromatous cases arise so late in life that very little extra hypertrophy can be expected, and, unless specially guarded against, the high peripheral resistance, which was the main cause of the regurgitation, continues to act, and the atheroma progresses; the prognosis is therefore bad though the amount of regurgitation is not great.

When aortic stenosis supervenes in a case with considerable regurgitation, it improves the prognosis by lessening the amount of regurgitation. Dangerous symptoms will often disappear and the patient's life be much prolonged. When a valve ruptures, the strain put suddenly on the heart is too great, dilatation of the left ventricle is extreme, and hypertrophy never properly compensates. If there is dropsy the first thing to determine is whether it is due to mitral disease mainly, or to dilatation of the mitral orifice by the extent of the aortic regurgitation. If due to mitral disease the pulse will be irregular and not very large nor collapsing, and the second sound will be heard in the neck; the prognosis will be then rather better than when due to giving way of the mitral valve through the amount of aortic regurgitation.

Treatment.

Far the most important time for treatment is at the onset in rheumatic cases. Children with growing pains or a pain in any joint should always have their hearts examined; the onset of endocarditis is so insidious. During the acute stage salicin or aspirin given in full doses appears to be less depressing to the heart than salicylates. Small repeated blisters to the first, second, or third spaces on the left side, as recommended by Caton, are distinctly useful, as also is potassium iodide after the temperature has fallen. When the aortic valve is affected, rest in bed is essential, not only until the temperature comes down to normal, but for at least six weeks after, and then a very gradual return to being up all day, and no exercise or work should be allowed for six months or more. If so treated the murmur and all signs of the regurgitation will in rare instances completely disappear; I have seen this happen in a case recently. But when the regurgitation persists, as it usually does, compensation i attained with as little dilatation as possible, and so more reserve is left for future contingencies.

In syphilitic cases potassium iodide tends to prevent the increase of the lesion, and also does good by lowering the vascular tension. Atheromatous cases need tonics combined with measures to reduce the peripheral resistance.

In all cases tonics such as strychnine, arsenic, formates, ammonia, and bark are most useful, and belladonna if there is palpitation. The bowels should be kept regular, but no violent purgatives must be given because of the danger of fatal syncope. Flatulent distension of the stomach should be watched for and treated, since it may bring on angina pectoris earlier than need be. Whenever there are symptoms of cardiac distress, rest in bed for two weeks to a month should be ordered, and the getting up after this must be gradual. The patient ought also to be warned of the extreme danger of any sudden exertion. Hypodermic morphia is the best hypnotic if the nights are bad.

If venous congestion or dropsy come on, digitalis combined with vascular dilators and diuretics is useful until these symptoms have been got rid of. Then, if the mitral and tricuspid breakdown was due to the amount of the aortic regurgitation, the digitalis must be at once stopped, since it is a dangerous drug to use in aortic regurgitation. Bleeding is never safe, but a few leeches may sometimes help the digitalis when there is venous congestion. For angina pectoris the vascular dilators, spiritus ætheris nitrosi, trinitrin, or erythrol tetranitrate are needed regularly, and capsules of amyl nitrite should be carried in case of an attack coming on. Arsenic or phosphorus and tonics improve the condition of the heart muscle and lessen the tendency to attacks.

Brighton.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON TWO CASES OF CEREBRAL HÆMORRHAGE ASSOCIATED WITH ANÆSTHESIA.

BY H. P. FAIRLIE, M.B., CH.B. GLASG.,
ANÆSTHETIST TO THE GLASGOW ROYAL INFIRMARY.

CASE 1.—The patient, a man aged 23 years, a labourer, was admitted to the Glasgow Royal Infirmary on March 8th, 1910, as a result of a severe injury to his left arm, occasioned by being caught between the rollers of a machine, and resulting in the complete destruction of the skin from the shoulder to the wrist. To allow of grafting this he was anæsthetised on three occasions, on the first and last by myself, and on the second by the house surgeon. Physical examination before anæsthesia revealed nothing abnormal. On the first occasion (March 24th) anæsthesia was induced by gas and ether; after 10 minutes a change was made to chloroform, administered on Skinner's face-piece. There was no difficulty of any kind, the anæsthesia lasting 25 minutes. On the second occasion (April 1st), of which I have no detailed note, the house surgeon gave chloroform on Skinner's face-piece. After induction, during which there was some struggling, the respirations became shallow and stopped. Artificial respiration was commenced and continued for about one minute, after which natural respiration returned and remained good during the operation, five grafts being applied. On the third occasion (April 23rd) chloroform was administered on Skinner's face-piece. During the first stage there was considerable excitement, with violent struggling, followed in six minutes by unconsciousness, abolition of the corneal reflex, medium pupil, good breathing and pulse, with slight cyanosis. The patient was allowed four or five breaths of air, after which chloroform was again applied. At eight minutes the patient was turned on his right side to permit of grafts being taken from the outer side of his left thigh. His left arm hung over and slightly pressed on the chest. At this minute the breathing suddenly became interrupted and gasping, then ceased, with dilatation of the pupils, livid pallor, and almost imperceptible pulse. The patient was at once turned on his back, his head was lowered, his tongue pulled forward, and artificial respiration by Silvester's method commenced. By this time the pulse was quite imperceptible and the cardiac impulse could be neither felt nor heard. Hot-water cloths were applied to the præcordium, and 30 minims of brandy and 1/60th of a grain of strychnine were injected hypodermically, but with the exception of one or two gasping inspirations the patient gave no further indication of life. A post-mortem examination revealed the following conditions:—Heart: normal. Lungs: some engorgement at base; no œdema. Brain: fresh hæmorrhage extending over both cerebral hemispheres downwards towards the base, more extensive on the left side. There was no hypertrophy of the lymphatic tissue.

CASE 2.—The patient, a woman aged 61 years, was admitted to the Glasgow Royal Infirmary on May 12th, 1910, with a diagnosis of carcinoma of the cæcum. Although for some time before the admission she had been losing flesh she was still very stout. Physical examination before anæsthesia showed no abnormality, except rather feeble heart sounds, but no valvular lesion. On May 14th she was anæsthetised by Dr. A. Stewart, house surgeon, the anæsthetic chosen being chloroform administered on Skinner's mask. The first stage was quiet, but before the patient had entered the second stage preparation of the skin for the operation was commenced, causing slight straining of the abdominal muscles and holding of breath. After five minutes' administration, when about two drachms of chloroform had been given, difficulty arose. Respiration ceased, with cyanosis and weaker pulse. The usual methods of resuscitation were adopted, as in Case 1, with the exception of the injection of brandy, and after artificial respiration had been continued for about seven minutes respiration was resumed and the pulse improved in volume. An attempt was made to continue anæsthesia with ether by the open method, but this gave rise to the same alarming condition, though artificial respiration was not called for, and the patient was sent back to bed without operation. She kept well for three days, when it was noticed that there was slowness in answering questions, with delayed comprehension and slight mental dulness. Later in the day (May 17th) paralysis of the left arm developed, with slight drawing of the mouth to the right side, and unconsciousness. On the 18th, there was a slight return of consciousness, the patient being then able to answer questions, otherwise her condition remained the same. After this date there was no opportunity for further observation as the patient left the infirmary.

The above cases draw attention to the association of cerebral hæmorrhage with chloroform anæsthesia, which, judging from the absence of reference to it in the current literature on anæsthetics, seems to be of rare occurrence. Dr. F. W. Hewitt in his text-book on the subject mentions it as a concomitant of ether anæthesia, where, owing to the action of ether as a circulatory stimulant, and also to the frequent occurrence of some degree of venous stasis in the early stages of ether administration by the closed method, it is more liable to occur. In the first of the above cases, where apparently difficulty arose and death resulted from primary circulatory failure, it is difficult to explain the hæmorrhage unless by ascribing it to raised arterial tension and rupture of a vessel during the period of struggling. In the second case, on the other hand, there was no struggling, and here the origin of the difficulty seems to have been primarily respiratory, with venous engorgement, and possibly resulting rupture of a small vein.

Glasgow.

BREAKING-DOWN GUMMATA OF LIVER SIMULATING TROPICAL ABSCESS.

BY G. S. THOMPSON, M.R.C.S. ENG., L.R.C.P. LOND.

THE following case is, I think, worthy of record, exemplifying as it does the value of the rule of administering anti-syphilitic remedies in all hepatic conditions which prove intractable or irresponsive to measures already invoked.

The patient, a male, aged 25 years, had been suffering for six months with pyrexia, sweating, "chills," lassitude, malaise, and latterly cough accompanied by "anchovy sauce" expectoration. Pain was present at first in the epigastric region, and later over the lower posterior aspect of the right side of the chest. When seen the patient looked severely ill, presenting the hectic appearance. Physical examination revealed a considerable area of dulness over the region of the right side of the chest posteriorly and below, as well as unilateral impairment of movement and a few moist sounds at the base of the lung. The temperature chart was characteristic of pus absorption. History as to dysentery or typhoid fever was quite negative, but as subsequently elicited there was a history of soft chancre five years previously, for which no anti-specific treatment was given, since syphilis was not suspected or suggested.

From the above facts, notwithstanding the absence of history of dysenteric infection, there appeared to be no doubt in my mind that a liver abscess was present. The patient was accordingly sent into the Kimberley hospital, and after making several negative exploratory punctures with a needle under anæsthesia pus was finally reached, and the cavity was then drained through the post-scapular line. The wound discharged freely, but the temperature still remaining up another abscess was suspected; the latter was opened by way of the first wound. The temperature then fell, and the discharge became less and less until the dressings were merely moistened by serous exudate, and expectoration had ceased. The patient was now allowed up, but in a few days' time the temperature began to rise again—notwithstanding the fact that good drainage was permitted from the liver—and although the dressings remained clean characteristic sputum reappeared. A third abscess cavity was therefore suspected and an endeavour was made to evacuate it through the wound. The expectoration continued, however, in abundance, and the prolonged persistence (about six or eight weeks) of the discharge again through both passages began to give rather a hopeless prospect for recovery.

In order to facilitate drainage through the lung the foot of the bed was now well elevated, and at the same time iodide

of potassium was administered. The result was striking and gratifying; in three days the sputum as well as the wound discharge began markedly to lessen in amount, and in a week's time both had ceased. This happy state of affairs persisted from that time onwards. The patient, after being in hospital over three months, was discharged quite well, and is now doing his work and feels like a normal individual again. He is also undergoing a course of anti-syphilitic treatment.

The following comments I think are justified by the above. The only thing that at all militated against the diagnosis of tropical abscess was the absence of a history of dysentery or typhoid fever, whilst the negative specific history (interrogation on which point, by the way, was hardly suggested by the condition) tended to mislead. The contents of the cavities were typically those of tropical liver abscesses. Yet it would appear that the lesions were breaking-down gummata of the liver. In favour of this view are the persistence, multiplicity, fresh deposits, and the response to iodide, for I have little doubt that the exhibition of this drug determined the related rapid change. The interesting feature is the striking simulation by tertiary syphilomatous liver disease to tropical abscess, if the above deduction be correct. I suggest the necessity of keeping this point in view in unprogressive cases, and even acting upon it previous to subjecting patients to operation; and the advisability in any case at least of giving iodide of potassium a trial in all liver diseases where other means fail, or before giving up hope.

St. Mary's Hospital, London, W.

NOTES ON A CASE OF INFECTION OF THE BASE OF THE BRAIN FROM A CARIOUS TOOTH.

BY S. W. MILNER, M.R.C.S. ENG.

THE patient was a married woman, aged 36 years, and had been healthy. On April 28th, 1910, she developed a "gumboil" from a decayed tooth in the left lower jaw and had neuralgia on the left side of the head. On April 30th and May 1st she had pain in the left temple and back of the head and also in both eyes and took to her bed. On May 3rd she called in a medical man, and he was in attendance until the 11th, when she was admitted to Gravesend Hospital. On the 4th when in bed she had "violent shaking." The right ear had always been rather deaf, but it was noticed that the deafness had become worse. On the 6th there was "swelling" of the right eye. On the 8th there was some delirium and the temperature rose to 106° F. On the 9th there was "swelling" of the left eye. On the 11th she was admitted to hospital.

On arrival at hospital she was conscious but exhausted and answered questions clearly, although very deaf. It was noticed that the right ear was totally deaf. With the left ear a loud ticking watch was heard at three inches distance. The right side of the face was paralysed. There was loss of sensation in the left side of the face. Both eyes were prominent, the right the more so, and both lids were red and swollen. The right pupil was dilated. Vision in the right eye was reduced to perception of light. The patient took fluid food readily. The temperature was 104° F. and pulse 106. There was a sensation of "something going round and round" in the head. The patient had very little sleep. The pulse remained good and there was no vomiting. There was a purulent discharge from both conjunctivæ. On the following day (May 12th) she had a rigor at 11 A.M., when the temperature rose to 105·6°. This was followed by delirium and restlessness. She took milk well. She was sleepless and delirious all night and at 3 30 A.M. became very collapsed. On May 13th the morning temperature was 101·2°, pulse 82, and respiration 40. She was delirious all day and vomited twice. She slept at intervals and perspired freely. She had no sleep at night and was delirious. She vomited green fluid three times and at 7.5 A.M. was very collapsed. She did not recover and died at 8.30 A.M.

A post-mortem examination was made. On opening the skull and removing the dura mater great engorgement of the vessels was noted. The membranes on the base of the brain from the optic chiasma in front to the under surface of the cerebellum behind and spreading laterally to the under surface of each temporo-sphenoidal lobe were green and necrotic and putrefying. On stripping off this membrane and the vessels the brain substance was normal in appearance and nothing abnormal was found on slicing the various parts of the brain. The dura mater was next removed from the base of the skull and the structures passing through the various foramina were examined. The left Gasserian ganglion was necrotic, as were the nerves leaving it. The right ganglion was healthy. The pituitary body was necrotic. The body of the sphenoid and both petrous bones were partially necrosed and greatly congested on section. In neither internal ear was pus found. The circular sinus and cavernous sinuses were thrombosed. There was pus in both orbits under the fibres of the levator palpebræ superioris. On pulling on the left inferior maxillary nerve as it left the skull through the foramen ovale pus was seen coming up around the nerve, and a probe passed easily along the nerve and beneath the mucous membrane of the left cheek—this being no doubt the track of the original infection from the tooth to the brain.

Medical Societies.

HARVEIAN SOCIETY OF LONDON.

Diagnosis and Treatment of Cystic Disease of the Breast.

A MEETING of this society was held on Oct. 27th, Dr. M. HANDFIELD-JONES, the President, being in the chair.

Mr. D'ARCY POWER opened a discussion on the Diagnosis and Treatment of Cystic Disease of the Breast by drawing attention to the difficulty which he had often experienced in diagnosing and treating cystic tumours of the breast. He stated that the classification of cystic disease was chaotic at the present time and offered for consideration the following scheme:—

(*A*) *Non-Inflammatory.*

(*a*) Innocent ... (1) Adenoma ... ... (i.) Ducts. (ii.) Acini.
(2) Fibroma... ... ... (i.) Pericanalicular. (ii.) Intracanalicular.

(*b*) Malignant ... (1) Carcinoma ... ... (i.) Duct papilloma. (ii.) Duct carcinoma.
(2) Sarcoma... ... ... (i.) Cystic. (ii.) Degenerating.

(*B*) *Inflammatory.*

(i.) Galactocele ... (1) Cyst single and simple.
(ii.) Mastitis ... (2) Cysts multiple.

(*C*) *Congenital*.... ... Lymphangioma.

(*D*) *Parasitic* ... ... Hydatid.

Cystic adenomata were well recognised tumours of the breast and called for little comment. Mr. Power gave short notes of two cases, and pointed out that in removing the tumour it was necessary to cut clean through the overlying breast tissue before any attempt was made to enucleate the adenoma. He thought that it was not necessary to remove every adenoma of the breast. Cystic fibroma of the breast, or Brodie's disease of the breast, occurred in an innocent form—cystic fibroma—and in a malignant form—cystic sarcoma. The innocent cystic fibroma of the breast was characterised by an overgrowth of connective tissue starting in the stroma round the ducts and acini—the pericanalicular form—or in the subepithelial tissue of the ducts themselves—the intracanalicular variety. Both tumours were associated with the formation of numerous cysts filled at first with clear serous fluid. The cysts were therefore due to obstruction of the glandular tissue, although in some cases there was microscopical evidence that the glandular epithelium had itself undergone cystic degeneration. The cyst wall in the pericanalicular form was often invaginated by the new growth of fibrous tissue until the cyst became a mere slit, and on section the tumour seemed to be solid until a probe was passed into the slits, when the invaginating growth could be turned out and the cyst demonstrated. In the intracanalicular form the cysts remained obvious and the growth sprouted into it as "a duct papilloma." Mr. Power illustrated his remarks by cases, and then went on to show that secondary changes might take place in the connective tissue of stroma of intracanalicular cystic disease. Malignant cystic disease of the breast attacked the same parts as cystic fibroma. It occurred in the forms of cystic sarcoma and duct cancer—the sarcoma corresponding with pericanalicular cystic fibroma and duct cancer being the correlative of the intracanalicular form. Cystic sarcoma was

at first a well-circumscribed swelling which grew like sarcomata in other parts of the body. The cysts were constituent parts of the growth and were not degeneration products. A case was given in illustration. Cystic sarcomata of the breast were to be distinguished from sarcomata in which the cysts were produced by degenerative changes. Duct carcinoma was always cystic, the cysts being either simple or multilocular. Mr. Power gave an example of the multilocular cystic form which had been recently under his care. Cystic disease of the breast connected more or less directly with inflammatory changes were of greater diagnostic interest and presented greater difficulties in treatment than the non-inflammatory forms which had just been considered. Foremost amongst these, and in many ways the simplest, was galactocele. It was generally the result of inflammatory changes occurring in the breasts of married women. Mr. Power gave the details of a case where it had followed an injury in a virgin breast. Chronic mastitis lead to the formation of a most interesting group of cystic tumours. The cyst in these cases might be single and simple, or the whole gland might present the appearance of a sponge when it was examined after removal. The single and simple cyst was sometimes placed so deeply or had so thick a wall that it was mistaken for a solid tumour, and every pathological museum contained examples of such cysts where the entire breast had been removed under the misapprehension of the existence of cancer. It was a cardinal rule, therefore, to incise every breast before amputation was performed, and incision was always preferable to puncture, because mere puncture might lead to an intracystic growth being overlooked. The most difficult cases to treat were those in which there were many small cysts the results of chronic lobular mastitis. Mr. Power read the notes of such which had lasted several years affecting first one breast and then the other. He concluded his paper with a brief reference to congenital cysts of the breast which he considered to be of the nature of lymphangioma.

Mr. E. H. SHAW agreed with Mr. Power as to the unsatisfactory nature of the classification of breast cysts, but did not think Mr. Power's proposed classification was quite suitable. He had tried to work out a simple scheme which would include all the cysts and at the same time retain most of the names at present used. It was as follows:—

I. Inflammatory.

A. Abscess ... ... (*a*) Acute. (*b*) Chronic (as tubercle).

B. Retention ... ... (*a*) Galactocele. (*b*) Serous, or simple.

II. Non-inflammatory.

A. With intra-cystic growths ... ... (*a*) Adenoma. (*b*) Papilloma (or so-called duct papilloma). (*c*) Carcinoma. (*d*) Fibroma (intra-cystic fibro-adenoma). (*e*) Myxo-fibroma. (*f*) Sarcoma (intra-cystic adeno-sarcoma).

B. "Breaking down" of new growths (*a*) Carcinoma. (*b*) Sarcoma.

C. Parasitic ... ... (*a*) Hydatid.

Mr. Shaw showed a series of photographic lantern slides illustrating the naked-eye and microscopic appearances of most of the above cysts. He had time only to enter into a detailed description of the serous or simple cysts, and expressed his belief that all these cysts arose in connexion with chronic mastitis; they were retention cysts. He demonstrated the gradual thinning of the lining epithelium and also the thickening and proliferation of cells which occurred in some of the breast acini. He did not believe there was such a condition as a lymphatic cyst of the mammary gland. He was strongly against puncture of the cysts for diagnosis and treatment, and showed specimens of carcinoma in the walls of such cysts. He pointed out that the so-called "duct" papillomata were also found in dilated acini, and preferred the term "intra-cystic papilloma." In many cases the tumours were really solid adenomata projecting into a cyst, and should be termed intra-cystic adenoma.

Mr. W. G. SPENCER said he first wished to thank the Harveian Society for the honour it had done him by an invitation as a visitor to take part in this discussion, and then offered his hearty congratulations to Mr. Power upon his excellent description of the pathological anatomy of the cystic tumours of the breast, so well supplemented by Mr. Shaw's demonstration of the histological appearances. He felt unable to enter upon questions of classification, for so little was known as to the causes of pathological development of these growths. It was so difficult to attach any precise meaning to the term "inflammatory" except in the condition where one could connect the cause with some micro-organism. When so-called inflammatory conditions were noted as preceding cancer there must be some peculiarity as distinguished from the inflammatory effects produced by known micro-organisms. Moreover, the word "serous" was applied to the contents of many sorts of cysts, whereas in only a few could the contents correspond to physiological blood serum. Thirdly, Mr. Spencer recalled that Kanthack termed papillomas connective-tissue tumours, viewing the stroma as the main feature of the growth. That view had been regarded as heretical, yet many of the intra-cystic growths referred to as papillomatous appeared to be chiefly composed of a connective tissue stroma. One could hardly limit one's view to these cystic tumours which had proved non-malignant, but must consider alongside them the number of cases of carcinoma which had at first been regarded clinically as benign. When cut out early enough for some breast tissue to persist outside the cancer there were changes to be found in that breast tissue like those present in benign tumours. Turning to the practical side of the matter, a puncture of a cyst, followed or not by injection, was often adopted, and the patients were said to have been relieved. But in how many instances were they cured? Were they seen later with advanced disease? Mr. Spencer did not feel sure that the practice was really justified by results; the cases should be very carefully watched after the puncturing. Mr. Power had referred to recurring forms of chronic mastitis. How long should they advise a woman to put up with it? One could not state with certainty whether she would be cured by waiting. Even although there were no signs of advancing disease at the moment, they could not exclude the possibility that new growth might ultimately ensue. Therefore he did not think that they should treat recurring mastitis for longer than a few months, after which time excision should be advised. In the case of circumscribed cystic tumours he was sure that it was wise to remove also a zone of the apparently healthy breast tissue around. Hence the words "enucleation" or "shelling out" did not express all that should be done. Even although the main tumour be circumscribed, if there was some definite change from the normal in the breast tissue around it, as seen with the naked eye, he would advise excision of the whole breast. The nipple could be left as Mr. Power had mentioned.

Mr. T. CRISP ENGLISH said that mammary cysts were almost always secondary to mastitis, or some other local disease, and that recognition of the primary condition was of essential importance; an exploratory incision should therefore be made in all doubtful cases. In cystic mastitis it was usually possible to excise the cyst-bearing area through a transverse incision below the nipple about two inches in length; this procedure left comparatively little deformity, and the results were excellent. He did not believe that the ordinary form of cystic mastitis involved any special predisposition to malignant disease.

Mr. G. E GASK said that he thought a classification of cystic tumours was badly wanted, and that the reason of the present confusion of terms lay in the misunderstanding concerning the histology of the intra-cystic growths. These were nearly always due to protrusion of the stroma or interstitial tissue into the cavity of the cyst and not epithelial growth, and this stroma might be fibrous tissue or fibrous tissue showing myxomatous or sarcomatous degeneration, hence the confusion as to the meaning of "Brodie's disease." As regards mastitis with cyst formation Mr. Gask thought that whenever the condition called for surgical treatment the whole breast should be removed, because, in his experience, a partial excision did not free the patient from neuralgic pain, and often further operation was required, and, moreover, certain cases were followed by the appearance of a carcinoma.

Mr. W. H. CLAYTON GREENE said he should like to add his thanks to Mr. Power for his valuable paper. He thought the description of the cyst with the different forms of intra-cystic growth was a very clear one. He should, however, like to ask Mr. Power which he considered the primary change, the cyst or the growth. He asked Dr.

Spilsbury about it that afternoon, who told him that he thought the connective tissue growth was the initial stage, a growth which led to a retention cyst in the acinus. Also he would ask if Mr. Power would allow the possibility of these neoplasms having an inflammatory origin. Mr. Clayton-Greene had often been struck with the histological similarity between the adenomata and fibromata and interstitial mastitis acknowledged to be of inflammatory origin, only in the former a small area of the breast was attacked, in the latter the whole organ. With regard to the removal of these simple tumours Mr. Clayton-Greene would agree with Mr. Spencer that it was always wise to cut them out clearly with a little of the surrounding tissue. If enucleated they sometimes recurred, and he had seen instances where they had turned out to be spindle-celled sarcomata, the "recurrent fibroid of Paget." It was often very difficult to tell from a section whether a sarcomatous change was or was not occurring in the stroma. With regard to general cystic disease and interstitial mastitis Mr. Clayton-Greene would touch on one point that had been raised—their relation to malignant disease. Some of the speakers regarded the condition as precancerous, a view which was held by the American surgeons, who associated the development of the adeno-carcinoma with this diseased condition of the mammæ. Reclus, on the other hand, denied the relationship, and treated the cysts by puncture and injection. It seemed as if they had two classes of case—one with large cysts, two or three, as a rule, which were rarely associated with a malignant change, and the other where the whole breast was riddled with cysts, and was shrunken and atrophied. The former he had not regarded as dangerous, but from what he had heard and seen that night he was inclined to alter his opinion. The latter, he thought, should be dealt with surgically by the method described by Mr. Power, by turning up a flap and dissecting away the breast tissue from the skin and nipple, which were then replaced. Both breasts usually suffered, though not necessarily at the same time. Mr. Clayton-Greene would like to ask Mr. Power if he had any experience of the cancer cysts described by the American surgeons—cysts with a thick wall containing blood, apparently a very malignant type judging by the reported cases. He had had one case himself this year. He entirely agreed with the need for exploratory incision in a doubtful case. With ordinary care there should be no risk of cancer cell infection, the whole mass could be cut out clean and then submitted to careful examination. He was often doubtful of the nature of a breast tumour, and he should reproach himself bitterly if he performed the modern operation for the removal of a malignant breast for a condition which did not require it. It was a very big operation—one of the largest in surgery. He was delighted to hear that the serous cyst did not exist. Its existence had been taken for granted by text-book after text-book, and it appeared to be merely a name given to a cyst from the character of the fluid, and owing to the fact that the epithelial lining had been destroyed in the preparation of the specimen. He had long looked for an example. He should do so no more. The serous cyst was dead; might it be decently interred under this mass of pathological evidence.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

The Significance of Vertigo.

A MEETING of this society took place at the Great Northern Central Hospital on Oct. 13th. In the absence of the President, Dr. T. J. Horder, the chair was taken by Dr. C. M. HINDS HOWELL.

The session was opened with an address by Dr. J. S. RISIEN RUSSELL on the Significance of Vertigo. He said that in the choice of a subject for the address he had been largely influenced by two considerations: one of these was that he supposed that his audience would be chiefly composed of men actively engaged in practice, who would be more likely to welcome something practical that might be of some immediate use to them in their work, rather than listen to a discourse which, although possibly brimming over with interest from the scientific standpoint, could not be said to offer anything that could be of practical value now, no matter what the possibilities for the future might be. The other reason that had guided him in the choice of vertigo was that he had seen so many patients suffering in this way in whom he believed that a wrong construction had been put on the case merely because the blood pressure happened to be high. Enough account had not been taken of the fact that such blood-vessels as lent themselves to palpation did not reveal abnormal thickening, that the retinal vessels were equally free from signs of sclerosis, as viewed by the aid of the opthalmoscope; that analysis of the urine failed to throw suspicion on the kidneys, or that the individual was of highly nervous temperament and not a little perturbed by the alarming sensations occasioned by the vertiginous seizures. An unduly hasty diagnosis of impending apoplexy was apt to lead to the patient being terrorised, purged, and dieted into a condition of nervous prostration that ultimately made him a fit subject for a "rest cure." He was far from wishing to belittle the importance either of vertigo or high blood pressure as evidence of arterial sclerosis and as warnings of impending calamities in the way of gross vascular lesions of the brain, but he felt sure that many people were doomed to a fate of the kind on insufficient data. A case was quoted, in illustration, in which the patient had received the grave verdict of impending apoplexy, and in which he had been treated into a condition of nervous prostration, when in reality the vertigo in his case was aural in origin. Some of the cases of "apoplectiform" labyrinthine vertigo were very alarming in their manifestations, and it was not surprising that they occasioned fear of more serious mischief. In this connexion he quoted a case of the kind in which cerebellar hæmorrhage had been suspected, but in which he was confident of his opinion to the contrary, which was confirmed by the subsequent progress of the case. This afforded him the opportunity of alluding to the fact that although vascular lesions of the cerebrum were so common they were comparatively rare in the cerebellum, a reason that should cause some hesitation before too confident a diagnosis of cerebellar hæmorrhage was made.

In his experience aural vertigo and neurasthenia were the two conditions, one or other, or both of which had obtained in cases in which arterio-sclerosis of the cerebral vessels with threatened apoplexy had been the unjustified diagnosis. Although the acute apoplectiform variety was rare, it was, of course, common to meet with the chronic slowly progressive forms of aural vertigo. The diagnosis was often made the more difficult owing to the fact that a certain amount of fulness in the head might be complained of, especially on the affected side, and all of the symptoms were influenced by changes of the position of the head. Moreover, evidences of arterio-sclerosis might be forthcoming owing to the fact that the aural condition was most common in persons who had reached the degenerative period of life in which arterial sclerosis was also most likely to be met with. It not uncommonly happened that a varying amount of neurasthenia became added, which was responsible for aggravation of all the symptoms. Neurasthenia alone might similarly occasion vertigo and a variety of cephalic sensations readily mistaken for those that result from arterio-sclerosis of the cerebral vessels, from which condition diagnosis might not be easy when the person affected had reached the degenerative period of life, and in view of the further fact that, as in arterio-sclerosis, posture might have a very notable effect on the sensations. The importance of vertigo as a symptom in epilepsy was next dealt with, and emphasis was laid on the difficulties that might arise in attempts to decide between epilepsy and aural vertigo, notably in some of those cases in which the patient was hurled to the ground with such suddenness in aural vertigo as to make him temporarily dazed, and thus made them uncertain in regard to one of the signs on which they placed most reliance in the differential diagnosis—viz., loss of consciousness in epilepsy as contrasted with its preservation in aural vertigo.

In dealing with cerebellar disease he showed how difficulties might arise where the diagnosis of abscess of the cerebellum was under discussion, owing to the similarity in the symptoms that might be manifest as a consequence of aural suppuration and its immediate consequences, short of suppuration in the cerebellum. The clinical phenomena on which a diagnosis must be based, led him to refer to the experimental researches that had supplied evidence of many of the signs that should be looked for when they were in search for cerebellar disease. The singular absence of many of these signs in recorded cases of cerebellar abscess was commented on, and while allowing for the possibilities of

compensation as revealed by the results of experimental ablation and of congenital defects of the organ, he could not help attributing some of the paucity of signs in these cases to a want of special knowledge on the part of the surgeon under whose care they most commonly came.

In discussing tumours of the cerebellum in relation to vertigo, he not only dealt with the physical signs that would justify a diagnosis of this kind, but also took the opportunity of drawing attention to the work of two of his colleagues (Grainger Stewart and Gordon Holmes) that had done so much in assisting them to decide whether the symptoms were due to an extra- or intra-cerebellar tumour. The number of cases that had come under his observation in which cerebellar tumour and disseminated sclerosis had been mistaken for each other compelled him to contrast the clinical pictures of these two affections, and in so doing he could not too strongly emphasise in support of tumour the importance of severe paroxysmal headache, vomiting, optic neuritis with choked disc, as contrasted with retro-bulbar neuritis, the absence of evidence of affection of the pyramidal tracts, objective defect of sensibility, and sphincter affection, all of which formed such important positives in disseminated sclerosis. In illustration of the confusion that might arise in diagnosis, a case in point was quoted where disseminated sclerosis had been suspected and in which an extracerebellar tumour was in reality responsible for the symptoms, a diagnosis that was confirmed by operation. By the aid of a lantern demonstration he was able to show how it happened that disseminated sclerosis might be responsible for the most intense vertigo as well as ataxy, owing to the distribution of the lesions; whereas affections like subacute combined degeneration of the cord, tabes, and Friedreich's ataxy, all of them liable to be confounded from the clinical standpoint with disseminated sclerosis, though responsible for ataxy, did not number vertigo amongst their symptoms. In dealing with conditions outside the nervous system responsible for vertigo he referred to a case of aortic regurgitation, in which headache and vomiting were supposed to be of gastric origin, but impairment of hearing in one ear, inability to move the head, or to turn the eyes much less the head to one side, associated, further, with pronounced nystagmus, greatly intensified by all such attempts at movement, left no room for doubt that the cause of the vertigo was central, if he might be permitted to include the labyrinth in this term. The case afforded an illustration of how impossible it might be to arrive at a positive diagnosis of the pathological lesion no matter how certain they might be of its localisation, for although tumour of the cerebellum was the diagnosis that had been arrived at by one distinguished authority who had seen the case, he was unable to reconcile this diagnosis with the facts. Headache had never been a notable symptom, and certainly nothing like that to be expected in tumour; there had never been the slightest suspicion of optic neuritis, although the case had continued for a long time; apart from the impairment of hearing and the nystagmus none of the cranial nerves were affected; and, what was even more than ever significant, the symptoms and manifestations, including tremor of the hand, had varied in a way that should suggest disseminated sclerosis rather than tumour. As against the latter diagnosis, however, were the age of the patient, well beyond that at which disseminated sclerosis was expected to begin, the complete absence of any evidence of affection of the pyramidal tracts, the absence of subjective or objective sensory defects in the limbs, and the absence of any disturbance in the action of the sphincter of the bladder.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Epithelioma of the Tongue.—Recurrent Enlargement of the Salivary Glands.—Fungus Affections of the Finger Nails.

THE first ordinary meeting of the ninetieth session of this society was held on Nov. 2nd, Dr. BYROM BRAMWELL, the President, being in the chair. The following were elected for the ensuing session: President, Dr. Byrom Bramwell; vice-presidents, Dr. W. Allan Jamieson, Mr. J. M. Cotterill, and Mr. C. W. Cathcart; councillors, Dr. James Ritchie, Dr. J. S. Fowler, Dr. John Cumming, Dr T. J. Thyne, Dr. Edwin Bramwell, Dr. R. J. Johnston, Mr. David Wallace, and Mr. J. W. Struthers; treasurer, Mr. J. W. Dowden; secretaries, Dr. Francis D. Boyd and Mr. Alexander Miles; and editor of Transactions, Dr. D. Chalmers Watson.

Dr. ALEXANDER BRUCE and Mr. J. M. COTTERILL exhibited a girl, aged about 10 years, with Acquired Hydrocephalus, cured by opening the foramen of Magendie. The girl had had acute post-basal meningitis in August, 1908, followed by recurrent severe headaches, vomiting, gradual impairment of sight, and optic neuritis. The left abdominal reflexes became abolished. There were recurring losses of control of the bowels and bladder, then extreme weakness, first of the left, then of the right leg. The stuporose condition increased, with complete blindness and separation of the sutures through distension of the brain ventricles. Mr. Cotterill at first punctured the lateral ventricles through the right coronal suture and drew off from four to five ounces of fluid, but without benefit. Then a large part of the occipital bone was removed and the foramen of Magendie, which had been closed by fibrous tissue, was reopened. The result was gradual, and practically complete recovery of motor power, sight, intelligence, and control of reflexes ensued.

Mr. ALEXANDER MILES showed a man, aged 60 years, after removal of the Gasserian Ganglion for Trigeminal Neuralgia. At the ages of 16 and 50 years he had suffered from similar attacks. The one for which he was operated on had lasted five years but was gradually getting worse, and for two years he had been unable to work. He presented a typical picture of tic douloureux. Besides the usual there were many extra points of extreme tenderness. The operation was done on June 17th, 1910, and the Gasserian ganglion with the second and third divisions of the trigeminal nerve was removed by a modified Hartley-Krause operation. The relief of pain was immediate and lasting.

Dr. FRANCIS D. BOYD exhibited a woman after Cerebro-Spinal Meningitis possibly of tuberculous origin. During the meningitis the patient lay comatose and squinting, with head retracted, vomiting, and early optic neuritis. On spinal puncture the fluid was found to be purulent. Von Pirquet's reaction was positive; no micro-organisms were found in the cerebro-spinal fluid. Treatment consisted in repeated lumbar puncture with 1 per cent. collargol injections into the cerebro-spinal canal, and the patient had made an excellent recovery.

Dr. BYROM BRAMWELL showed a case for diagnosis. It was that of a man aged 20 years, a painter, with no history of plumbism; the family history was good. The disease had gradually progressed during the past year. Both legs were now very weak, as also was the left arm; the small muscles of the feet, hands, forearms, deltoids, &c., were atrophied. The pectoral muscles, latissimus dorsi, and left elbow were contracted; the deep reflexes were markedly exaggerated; double Babinski's sign was present; and pes cavus with blueness of the hands and feet were evident. There were no fibrillary twitchings or affection of the bladder or rectum. Slight nystagmus to the right was noted, but no reaction of degeneration. The case was like one of lateral sclerosis or the peroneal type of progressive muscular atrophy.

Dr. HARRY RAINY showed for Dr. G. A. GIBSON a case of Bulbar Paralysis which had come on within a few months in a man aged 57 years. In his youth he had served in the army and had afterwards been a labourer. He acquired lues when in the army and a few months ago began to have trouble in speech and swallowing. At present he has atrophy and fibrillation of the tongue, with feebleness of the lips and tendency of fluids to escape through the nose. His speech is very imperfect, both articulation and phonation being impaired. The anterior nuclei seem to be intact. The case is one of chronic polio-encephalitis inferior, with extension downwards below the ordinary seats.

Professor F. M. CAIRD read a paper on Epithelioma of the Tongue, a Review of 60 Hospital Cases. He said that carcinoma of the larynx, so long as it was contained within the limits of its cartilaginous box, and carcinoma of the sigmoid flexure enveloped by a protecting investment of peritoneum, resembled each other from an operative point of view in so far as a relatively favourable prognosis might be given in regard to the ultimate result. On the other hand, the final issue after surgical interventions which were concerned with carcinoma of the tongue and of the rectum was more uncertain, and recurrence was very liable to take place. This return was specially favoured by the relation of the muscular planes involved, the anatomical distribution of the

lymphatics, and by the lack of a defensive environment. The disease generally began as a local induration or a hard elevated area on the external border of the tongue; the covering epithelium gave way, an ulcer formed, and a most characteristic neuralgic pain referred to the ear and temporal region distressed the patient. Enlargement of the lymphatic glands of the neck ensued. If the trouble were situated near the root of the tongue or if it spread to the floor of the mouth the greater was the inconvenience felt by the patient in swallowing, masticating, or speaking. There might be a troublesome flow of saliva and the breath acquired an offensive odour. The greater the fixation of the tongue the greater was the difficulty in protruding the tongue. Antecedent irritation had long been recognised as at least predisposing to the development of carcinoma. Of the 60 cases no less than 38 gave a definite history of some local irritation; thus 27 ascribed the disease to ragged teeth; 18 had already had the offending teeth extracted and in some instances had derived a temporary amelioration of pain; and 7 came with ragged teeth *in situ*. Three blamed a badly fitting toothplate and 2 were convinced that the ulcer arose where the end of their pipe rested. Three had made a rather prolonged use of caustics for what had been apparently simple conditions and 1 had scalded her mouth. Tobacco had been branded as a possible factor. Of the 54 male cases not one was a non-smoker. Twenty used a pipe in moderation and 11 to excess. In regard to alcohol 3 were abstainers, 8 drank in moderation, and 14 confessed to excess. Syphilis accounted for none of the manifestations and only 4 males acknowledged infection. Leucoplakia was only noted three times in the tongue or cheek. Nineteen patients gave no history of antecedent irritation; 2 were practically edentulous. A hereditary history of carcinoma was elicited from 5 patients. A consideration of the above tended to confirm the view that a relationship obtained between antecedent irritation and malignant disease, and the plea for greater attention to the teeth in later years was urged. Diagnosis rarely presented any difficulty, and if doubt existed it was readily solved by a microscopical examination (which, indeed, should be employed in every case). Only in 2 female cases did such an examination prove negative, and in one of these cases the patient died five months later from fungating cervical glands, and in the other six months later the lingual epithelioma was too advanced to allow of further operation. The only treatment which held out any prospect of cure was that of the knife. There was no other treatment. The so-called radical measures generally constituted a two-stage operation. They were greatly indebted to Mr. Butlin, who advocated a systematic attack on the adjacent lymphatic areas, and also brought their operative procedures into line with those practised in other parts of the body. The first stage consisted in removal of one-half of the entire tongue after the manner of Whitehead or of Syme. The second, following in about 10 days, was Butlin's extensive dissection of the side of the neck affected from the angle of the jaw to the sterno-clavicular articulation. This required that the entire sheet of connective tissue exposed, including the platysma, lymphatics, submaxillary and portion of the parotid salivary glands, and even the internal jugular vein itself, if need be, should be cleared away. Such extensive operations were associated with a remarkably low mortality, so low, indeed, that despite their uncertainty as to the ultimate result they were justified in urging operation. The chances of cure were not, indeed, as good as those which followed after pylorectomy for gastric carcinoma, but the risk incurred was not nearly so great. This relative freedom from risk was largely due to the free drainage and vascularity of the parts operated on. Local recurrence in the tongue was a rare after event, the patient's life was at least prolonged, and he was at least spared the misery and suffering which a fungating and loathsome mass of disease in the mouth entailed. The local recurrence in the glands of the neck was a less trying termination to life. Partial operations, in which the primary lingual disease was alone removed while the secondary glandular implication was left untouched, might be perfectly justified and indeed welcomed. For several years he had been led to perform the first stage under local anæsthesia, and with great advantage. After infiltration of the tip of the tongue with ½ per cent. solution of cocaine and adrenalin, two stout silk ligatures were carried through the tongue on each side of the middle line, half an inch from the tip, and the tongue pulled forward and further infiltration proceeded with. By this method anatomical details and vessels were clearly revealed and no gag was required, the patient being able to assist the surgeon by rinsing out the mouth. If it were necessary to divide the jaw at the symphysis, as in Syme's operation, the anæsthetic solution might be injected into the periosteum. By this mode of operation such general control was exercised that the adjuvant laryngotomy so strongly recommended might be discarded. The ease with which the patient speaks and feeds immediately after the operation was as striking as the slight discomfort which was experienced during the operation. The only disadvantage was an oozing of blood which made it necessary to secure all bleeding points. Iodoform and boric powder were applied to the raw surfaces. Should the disease have extended to the alveolar margin the whole depth of the jaw is not removed, but the hard sclerosed lower border was left, so preserving an intact mandibular arch, and in no case had he observed any recurrence in this bar of bone. The second stage required general anæsthesia, and if the oral cavity was opened into, sepsis of the upper part of the incision resulted, and so free drainage was essential. He generally removed the submaxillary salivary gland, the associated facial artery, vein, and lymphatics *en bloc*. If this salivary gland were spared, it underwent cirrhotic change which simulated a return of the disease. The average age of the patient was 49 years; the extremes were 23 and 73. Twelve cases were inoperable. There were seven fatal cases, chiefly from pneumonia, and all were very severe operations involving the removal of the entire tongue, tonsils, pharyngeal walls or adjacent areas of the entire lower jaw. Only 16 patients at present survive; the periods since operation vary from 20 months to 8 years. Such poor results were apt to make one despondent as far as the prospect of a radical cure was concerned, but better results might be obtained were a more radical form of operation employed. The results in private patients were slightly better than those now quoted.—Mr. C. W. CATHCART said that Professor Caird's results would compare very favourably with those of other surgeons. There were great varieties in the malignancy of carcinoma, and the removal of glands was a comparatively recent procedure. He thought that a preliminary laryngotomy was of great advantage, as it made the operation easier and safer.—Professor ALEXIS THOMSON said that Professor Caird's results were better than most surgeons could show. He thought that the operation should be done in continuity—tongue and neck. It required great courage on the part of the physician as well as the surgeon to tell a patient that a big operation must be done for an apparently trivial affection. Hardly any case survived for longer than three years after operation. He thought that the pathologist was often badly treated in only obtaining a small fragment for examination; he advocated the excision of a good piece of the growth for examination.—In reply, Professor CAIRD said that every form of carcinoma of the tongue was most malignant. The use of local anæsthesia did away with the necessity for laryngotomy. Recurrence did not usually take place in the floor of the mouth but at the root of the neck or clavicle.

Mr. D. M. GREIG read a paper on Recurrent Enlargement of the Salivary Glands. He said that the paucity of literature on the subject argued that this affection was of little importance. When the parotid glands were alone affected an erroneous diagnosis of mumps might be made. In an experience of 1500 cases of glandular enlargement Mr. Greig had notes of but five cases of recurrent enlargement of the salivary glands, and of these three were submaxillary and two parotid. 1. One case of submaxillary enlargement occurred in a healthy male aged 24 and recurred each spring. 2. A female, aged 23, suffered from submaxillary enlargement on the right side during eating or prolonged talking. 3. A woman, aged 44, exhibited recurrent swelling of the right submaxillary gland. 4. A female, aged 35, had a recurrent swelling of the right parotid, each attack being preceded and accompanied by fever. 5. A girl, aged 19, suffered from a similar affection. The parotid affection seemed to be the more common and tended to become bilateral. Many recorded cases of recurrent swelling of the parotid glands were said to have followed an attack of mumps. Many cases of glandular enlargement developed into tuberculous glands. Mr. Greig discussed the differential diagnosis of recurrent swelling from mumps and also the etiology of the former affection.

The rapidity with which the swelling generally occurred suggested a calculus, and it was possible that many such cases of recurrent swelling were mistaken for this blocking of the duct. Much allied to this recurrent swelling was the condition known as sialodochitis fibrinosa, where the duct became blocked with mucopurulent secretion. The condition of recurrent swelling would seem to be one of adult life, when at this period nervous affections were common, when secretions were prone to undergo alteration, where there might be digestive troubles or carious teeth. Treatment seemed to be of little moment. If the attack were exceedingly acute, incision might be necessary. Morestin and others recommended catheterism of the duct, and in chronic cases the injection of iodine solution along the canal.

Dr. R. CRANSTON LOW read a communication on Fungus Affections of the Finger-nails. That such diseases are more common than is generally supposed is borne out by the fact that within the last three years Dr. Low had observed no fewer than 19 cases. The cases fall into three groups: (1) ringworm; (2) favus; and (3) those due to other fungi of unknown origin. There were 16 of the ringworm variety, and these showed a marked predominance in the female sex, only two being in males. This predominance was difficult to explain; possibly the frequent washing of infected clothes might account for the predominance. Ringworm of the nails might occur at any age, the youngest of Dr. Low's cases being 10 and the oldest 58 years; the majority being between 20 and 30. This age incidence corresponded more nearly with that of tinea corporis than of tinea capitis. Ringworm of the nails was very rare in children with ringworm of the scalp. This infrequency might be partly due to the fact that ringworm of the nails was always due to the large spore fungus; but even in children with large spore tinea of the scalp, nail affections were very rare. The explanation might possibly be that tinea capitis so rarely caused itching that there was no tendency to infect the nails by scratching. The source of infection was difficult to trace, but one patient was infected whilst treating her own child's head for large-spored ringworm. Two of the cases were husband and wife and other two were sisters. Possibly spoon-shaped nails were more liable to ringworm affection. The duration of the disease varied from three weeks to seven years, the average being four years. The number of the nails affected varied from one to seven. In one-half the cases both hands were affected. Diagnosis was comparatively easily made as the appearance of the nails was constant. The splitting up and splintering of the free margin was characteristic, and the colour of the nails varied from a yellow-white to brown or black colour. In nearly all Dr. Low's cases there were definite zones presenting different colours and appearances. The infection seemed to take place from the under surface of the free margin. At the tip the nail became undermined, dark in colour, and softer than normal. The disease slowly spread up the nail which broke off in splinters. Then came a light yellow zone longitudinally striped with darker lines, and still further up there was a dark yellowish-red zone which showed little tendency to split up. The latter seemed to Dr. Low most characteristic of the condition and represented the spreading edge where the infection was just commencing. In addition there was also in many cases a heaping up of the nail into irregular prominences with dark brown depressions, and in such cases probably the nail bed was also affected. In many cases the lunule had disappeared and the tissues at the base of the nail were red and swollen. The diagnosis was confirmed by microscopical examination of pieces of the nail in liquor potassæ. The fungus appeared as rows of square spores arranged in characteristic rows. If not found in one specimen others should be examined. Cultures were made in six cases and yielded three different kinds of large spored ringworm fungus—viz., trichophyton acuminatum, rosaceum, and crateriforme flavum. This was the first occasion in which the last named trichophyton had been found in ringworm of the nails. As to treatment it was difficult, but all methods had for their object the softening and removal of as much of the diseased nail as possible, and the application of a continuous antiseptic dressing. The best results were obtained by Harrison's method—i.e., after daily scraping, the application of a solution of pot. iod. ℥i. in liq. potassæ and aq. dest. āā ℥ss. for half an hour on a piece of cotton wool. After this a solution of corrosive sublimate was applied for 24 hours and the finger covered with an indiarubber finger-stall. The nail became black and so soft that it could be removed. A new method devised by Dr. Norman Walker was that of applying ordinary Fehling's solution to the nail on lint and covering it with a finger-stall for a day or two. The nail by this time had become so soft as to be easily removed by forceps. After this a solution of copper sulphate (10 grains to 1 ounce) was used as a continuous dressing. Two cases of favus of the nails were met with in children who had already favus of the scalp; the nail was yellower in colour and more raised than in ringworm. From another case where the disease had lasted ten years, a peculiar fungus was obtained which differed microscopically altogether from either ringworm or favus. The culture also did not correspond to any of the common fungi and further examination was necessary.—Dr. W. ALLAN JAMIESON, Dr. NORMAN WALKER, and Dr. FREDERICK GARDINER took part in the discussion.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Presidential Address.—Exhibition of Specimens and Cases.

THE first meeting of the session of this society was held on Oct. 28th, Dr. A. CHRISTY WILSON, the President, being in the chair.

The PRESIDENT read his opening address on Tuberculosis, its Prevention and its Diagnosis and Treatment by the Use of Tuberculin. He was of opinion that the balance of evidence was in favour of the identity of human and bovine tuberculosis, and that it should be the duty of the State to discover tuberculosis in living beasts. The use of tuberculin, which was supplied free by the Board of Agriculture, was at present entirely voluntary. By its use many apparently healthy animals were found to be tuberculous. In Denmark the regular procedure was much more efficient in this respect than in our own country, tuberculous cows being isolated and kept under observation by State veterinary surgeons. He strongly urged the necessity for the isolation of advanced cases of tuberculosis and the necessity for more systematically carrying this out. He did not think that the present modes of sanatorium treatment were entirely satisfactory, many cases being discharged as cured from one sanatorium only to enter another. He advocated the employment of inexpensive wooden huts in the construction of sanatoriums, which could be erected in every district with comparatively little expense. He then considered the various tests which had been made to determine the presence of tubercle, and in his experience had found von Pirquet's more accurate and safer than Calmette's. The subcutaneous method, however, was the most accurate and precise. He much preferred making his tests with Beraneck's T.B.K. 1 tuberculin which he had used in a large number of cases, mainly surgical. He thought that Beraneck's T.B.K. 1 tuberculin was much preferable to Koch's new tuberculin, and if it were more widely employed as a therapeutic agent tuberculin treatment would gain in popularity. He quoted illustrative cases of improvement that had followed the use of this tuberculin. In conclusion, he thought that it was not necessary to control injections by the estimation of the opsonic index.

Mr. H. COLLINSON showed a specimen of Traumatic Rupture of the Spleen successfully treated by splenectomy. A labourer was kicked by a horse over the left costal margin; this was followed by hæmaturia and signs of intra-abdominal hæmorrhage. At the operation a large retro-peritoneal hæmorrhage was present over the left kidney.

Dr. R. BEATTIE showed a Mass of Hair which he had successfully removed from the stomach of a girl and which formed an exact cast of the organ and weighed 2½ pounds. Before the operation a hard gastric tumour was made out.

Mr. MICHAEL A. TEALE showed a child who had sustained Slight Concussion of the Brain. This was followed by swelling of the nasal half of each optic disc and marked rotatory nystagmus of a temporary nature.

Mr. H. LITTLEWOOD showed a Small Spirit-level and a Pencil-case successfully removed from adult male bladders.

Mr. C. H. GREENWOOD showed a Liver from a case of Portal Cirrhosis in a child who had been treated by fibrolysin. Microscopic appearances showed that softening of the fibrous tissue was taking place.

Dr. F. RITCHIE SINTON showed a specimen of extensive Ulcerative Colitis from a patient, aged 23 years, who had had intermittent diarrhœa, tenesmus, and passage of blood and mucus in the stools for 16 months. Death was due to iliac and pulmonary thrombosis.

Dr. W. H. MAXWELL TELLING showed a case of Myasthenia Gravis in a young girl. There were severe bulbar symptoms, the weakness of the pharyngeal muscles leading to choking attacks during meals. There was also marked weakness of the limbs. Considerable improvement of the bulbar symptoms had taken place.

Cases and specimens were also shown by Dr. C. OLDFIELD, Mr. J. F. DOBSON, Dr. A. BRONNER, Dr. T. WARDROP GRIFFITH, Mr. WALTER THOMPSON, Dr. T. CHURTON, Dr. A. G. BARRS, Dr. J. B. HELLIER, and Dr. E. F. TREVELYAN.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Presidential Address.

A MEETING of this society was held on Oct. 26th, Dr. A. W. RUSSELL, the President, being in the chair.

Dr. J. NIGEL STARK showed: (1) An Ovarian Cyst; (2) Hydrosalpinx; (3) Fibroids of the Uterus; and (4) Malignant Disease of Both Ovaries.

The PRESIDENT showed: (1) A Uterus with Malignant Disease at the Fundus; (2) Extra-uterine Pregnancy; and (3) Two Fibroids of the Uterus.

Dr. W. D. MACFARLANE showed an Adeno-carcinoma of Both Ovaries.

Dr. A. LOUISE MCILROY showed a Photograph of an Eight Months Fœtus with Enormous Hypertrophy of the Thyroid Gland.

Mr. D. DUFF showed a Fibroid of the Uterus.

Dr. A. M. KENNEDY showed: (1) The Liver and Kidneys from a case of Eclampsia; (2) Liver with Profuse Capillary Hæmorrhages from a case of Eclampsia; and (3) the Brain from a case of Eclampsia.

Dr. RUSSELL delivered his Presidential address on Prophylaxis in Obstetrics. In his introductory remarks, he referred to the fact that the society had now completed the first 25 years of its existence, and suggested that some suitable means should be taken to commemorate the event. One or two special points in its history were recalled, particular note being taken of the distinguished obstetricians and gynæcologists who had in turn held the office of honorary president, and of the benefit it had been to the society to observe this custom. It was intimated that Professor J. Whitridge Williams of Johns Hopkins University, Baltimore, had accepted election as honorary president for the next two years. The President, in coming to the address proper, said that though no special reference was made to it in literature, prophylaxis was the central principle of the art of obstetrics, the ideal towards which the true obstetrician must constantly strive, the persistent effort he must always make, to maintain the physiological character of childbirth. He pointed out that prophylaxis in obstetrics had to begin in the infancy of the future mother, for it was then that the seeds were sown that provided in after years a crop of cases of distorted spine and contracted pelvis. It was necessary to continue one's vigilance through the periods of girlhood, with its risks connected with school life and faulty development, puberty with the possibility of derangement of menstrual function, and adolescence with its perils, both physical and moral. He emphasised the need for early instruction regarding the reproductive functions. The principle of prophylaxis or prevention of complication was then traced and illustrated throughout the course of pregnancy in relation to constitutional diseases and uterine derangements, careful measurements of the pelvis, examination of the urine, choice of operative interference when such is necessary, the precautions necessary in handling or examining the patient. The subject was completed by showing the place of prophylaxis in labour and in the puerperium with regard to the promotion of spontaneous labour, the time to operate, the avoidance of such complications as hæmorrhage, sepsis, subinvolution, and uterine displacement.

Dr. J. MUNRO KERR (past President) thanked Dr. Russell on behalf of the Fellows of the society for his very interesting address. In his remarks he said that Dr. Russell had brought forward all the important conditions that might be prevented by prophylaxis. He had always been struck by the extremely broad-minded manner in which the President had attacked all obstetrical problems. Dr. Kerr congratulated Dr. Russell on his results on the operation of the induction of labour, and was with him in all that he had said on the measuring of pelves before labour set in and on the repeated examinations of the urine during pregnancy.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of the Pathological Section of this institution was held on Nov. 3rd, Dr. T. R. Bradshaw being in the chair.—Dr. E. Stevenson and Dr. R. E. Harcourt showed a specimen of Endothelioma(?) of the Eye.—Dr. Harcourt showed a culture of Aspergillus Niger, growing upon a lemon, isolated from the ear. The ear had been affected for two years, and recently the external auditory meatus was partly filled with pseudo-cholesteatomatous layers interspersed with black material.—Dr. K. A. Grossmann showed an Intra-ocular Melano-sarcoma of the Ciliary Region of about six weeks' duration. The eye had received a severe electric shock shortly before illness began. Perhaps this had stimulated the growth of a small dormant tumour.—Mr. R. Thelwall Thomas showed a Retro-peritoneal Tumour weighing 22 pounds, microscopically a spindle-celled sarcoma, which was successfully removed from a patient who was still living, four months after the operation; also a recent Malignant Growth occurring in an intracystic papillomatous tumour of three years' duration.—Dr. J. Lloyd Roberts and Dr. D. Moore Alexander showed a Carcinoma of the Pancreas and Liver from a man aged 23 years.—Dr. Blair Bell and Dr. Ernest Glynn showed microscopical specimens of Calcareous Secretions in the Ovary of a patient aged 49 years. Concretions in the ovary were of two kinds—calcareous and those due to coagulated proteins, mixed with acid hæmatin. Both varieties probably arose in connexion with the Graafian follicles and were extremely rare.—Dr. N. P. Marsh, Dr. H. Armstrong, and Dr. Glynn showed two cases of Pyloric Stenosis from Infants which was due to muscular hypertrophy.—Dr. Glynn also showed lantern slides of Spirochætæ demonstrated by the "Burri" Indian ink method. He drew attention to the enormous number of the spirochæta refringens sometimes encountered in balanitis.—Dr. O. T. Williams read a note on the Estimation of Chlorides in Urine, pointing out the need of a more routine use of the method in cases of nephritis, so as to save the administration of salt-free diet in cases where there was no chloride retention. He also demonstrated the use of Sahli's glutoid capsule in the diagnosis of pancreatic diseases, showing its uses and its limitations.—Dr. Stenhouse Williams and Dr. Nauss read a note on the value of Rabbit Leucocytic Extracts in the Protection of Guinea-pigs from Anthrax Infection. The leucocytes were prepared according to Pettersson's method and were inoculated in some cases simultaneously with the infecting organisms, in others at intervals of 24, 48, and 72 hours after the inoculation with anthrax. In all cases the extract was found to exert a marked protective influence, many of the guinea-pigs living for prolonged periods, though all the controls were dead within six days.—Mr. Moore Alexander stated that leucocytic extract had been used in the treatment of acute infections in man. The diseases treated had included pneumonia, with or without empyema, epidemic meningitis, streptococcal endocarditis, &c. In the majority of cases so treated the results had been immediately and strikingly beneficial.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 27th, Mr. A. W. Cuff, the President, being in the chair.—Dr. A. G. Yates showed a patient, aged 41 years, with Chorea. In July, 1910, he began to suffer from a sharp stinging pain in the right shoulder. Shortly afterwards he noticed irregular movements in the hands which later spread upwards and involved the arms and head. He had now slight lateral nystagmus and constant pain above the right clavicle in the region of the brachial plexus. The knee-jerks were slightly exaggerated. In other respects he appeared to be healthy. His sister had suffered in the same way for the last 20 years.—Mr. W. S. Kerr showed the specimen from a case of Innominate Aneurysm causing Asphyxia from Tracheal Pressure. The patient, a man, aged 34 years, who had had syphilis, was

admitted to the Royal Infirmary for urgent dyspnœa. A laryngotomy and passage of a small catheter gave temporary relief. The trachea was flattened by the tumour.—Mr. G. H. Pooley read a paper on Squint. After shortly discussing the history of squint, he referred to the importance of the fusion sense in maintaining the proper position of the axes of the eyes, and pointed out that when the fusion sense was weak errors of refraction such as hypermetropia produced over-accommodation for near objects, and owing to the close relation between the centres in the brain for accommodation and convergence, over-convergence was produced. The fusion sense not being strong enough diplopia did not cause much trouble and the brain learned to disregard the impression from one eye. The causes of loss of fusion sense were not known, but were supposed to be associated in some cases, at any rate, with defects of the auditory apparatus or the labyrinth and allied to nystagmus, or to be simply due to developmental error in those association bundles which are late in receiving their myeline sheaths, or in the centres which they join up. He pointed out that it was necessary to undo the mischief step by step: first, to correct the error of refraction, then to occlude or atropise the fixing eye until the power of fixation returned to the squinting eye. He found in the cases which he investigated that 75 per cent. of the squinting eyes were amblyopic, and in these cases it was advisable to occlude or atropise the fixing eye for from 12 to 18 months or until good sight had returned to the amblyopic eye. If these had not already become straight, then operative measures might be successfully employed. A classification of squint was given and some pathological conditions associated with paralytic squint with amblyopia were shortly referred to. An appeal was made to educate the public in the importance of amblyopia and its treatment. Statistics from 100 cases were given.—Mr. R. Favell showed a specimen from a case of Cæsarean Section for Accidental Hæmorrhage.—Dr. A. E. Barnes showed a Tumour of the Pons, the nature of which had not yet been definitely determined.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 2nd, Mr. W. Morley Willis, the President, being in the chair.—Mr. H. B. Tawse showed the case of a man 30 years of age with Congenital Occlusion of the Right Posterior Nares by a Bony Plate, causing Complete Nasal Obstruction on that side. He had also partial nasal obstruction of the left side of the nose due to a deviated septum.—Mr. Morley Willis then delivered his Presidential address on "The Significance of the Rigid Abdomen." He regarded this as one of the most important of all clinical signs in the diagnosis of an acute abdominal lesion. The abdominal parietes were innervated by the last six dorsal nerves, which through their sympathetic connexions supplied the abdominal viscera. Cutaneous hyperæsthesia, as worked out by Head, by its position served to help to diagnose the particular lesion. In most cases there were various other clinical signs to help the diagnosis, but very often the sole sign was abdominal rigidity. It was an early sign, and if they waited for further clinical manifestations an operation might prove unsuccessful. Illustrating his remarks, the President related the case of a boy, aged 16 years, who, four hours before being seen, was seized with sudden acute abdominal pain. The only physical sign was the abdominal rigidity. At the operation a perforation of the duodenum was discovered. In another case of a girl with a perforated gastric ulcer rigidity of the abdomen was the only sign. In any severe disease of the peritoneum reflex abdominal rigidity was at once caused. One fallacy was that in certain types of pleural disease abdominal rigidity was present. However, in these cases the temperature was usually higher and the respirations were more rapid and generally "catchy" at the end of inspiration. Finally, he laid it down as a good surgical axiom that the necessity for operation was urgent in exact proportion to the intensity of the abdominal rigidity.—A discussion then took place in which Dr. F. H. Jacob, Dr. C. H. Cattle, Dr. Parry Jones, Dr. H. Michie, Dr. K. Black, Dr. A. Stanley Green, Dr. J. A. O. Briggs, and Dr. W. Hunter took part. Several of these gentlemen related cases in which abdominal rigidity was absent, although the conditions were urgent; others had seen cases where abdominal rigidity was present, but the cases had recovered without surgical treatment.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 4th, Dr. Leonard Williams, the President, being in the chair.—Dr. N. S. Finzi read a paper on the Radium Treatment of Cancer. Having described briefly the physical characteristics of the α, β, and γ rays, he pointed out that these rays were given out in all directions even from flat surface applicators, and therefore to get the best results it was advisable that the radium should be surrounded entirely by the tissue of the growth. The intensity of the radiations varied inversely as the square of the distance, and this fact imposed some limitations in the treatment. Both β and γ rays exerted a selective action on cancer cells, so that the same dose which was innocuous to a healthy tissue would destroy the cancer cells, but the γ rays were much more selective than the β, and therefore it was necessary to use metallic filters to cut off the majority of the β rays. The latent period of the β and γ rays was different. In some cases the absorption of a primary growth led to some retrogression of metastases, but the treatment of every deposit that could be reached was, nevertheless, advisable. The class of case suitable for treatment depended on (1) the microscopical structure, (2) the position and size of the growth, and (3) the constitution of the patient. It was necessary to treat the whole tumour thoroughly with filtered rays, to use as much radium as possible, and to give one maximal dose every six weeks. In 64 completed cases of malignant growths there were seven cases in which the growth had completely disappeared. They were in the lip, breast, uterus, prostate, rectum, and œsophagus, and most of them had the diagnosis confirmed by microscopical examination. He had a further 23 cases still under treatment, of some of which he was very hopeful. Relief of pain and discharge was a marked feature even when the growth did not disappear. Rodent ulcers were practically always curable.

Reviews and Notices of Books.

Accidents in their Medico-legal Aspect by Leading Medical and Surgical Authorities. Edited by DOUGLAS KNOCKER, Barrister-at-Law. London: Baillière, Tindall, and Cox; and Butterworth and Co. 1910. Pp. 1254. Price 30*s*.

DURING recent years the amount of litigation under the Workmen's Compensation Act has developed to very large proportions. In all the cases the medical element is naturally of the greatest importance. The medical witnesses have to be questioned by members of the legal profession, and it is therefore necessary that the barristers and solicitors engaged should have some knowledge of the scientific issues involved. The ordinary medical text-books and treatises are not always easy for other than medical practitioners to fully comprehend, and if sentences are removed from their context confusion is likely to arise. Mr. Knocker has therefore made himself responsible for the volume now before us, the general aim of which is to make lawyers and medical men understand each other in their mutual relations. The labour of editing such a vast work must have been enormous, but Mr. Knocker is a barrister in active practice, and has had a large experience in the nature of the information required. He has been careful to avoid questions of purely academic interest, and has only included matters of actual importance, and by these limitations he has enormously increased the practical value of his work.

The book is divided into three sections—the legal part, the medical part, and the case guide. An index covers all three parts. The legal part has been written by Mr. Knocker himself. It is not intended to be exhaustive; all that is claimed for it is that it gives to medical men a short statement of the law on matters of interest to them. Reference is made to numerous cases, and this will afford help to lawyers by leading them at once to the line of cases they desire for various points in the law of accidents. An important matter touched upon is that of contributory negligence. It is pointed out

that circumstances of the nature of contributory negligence on the part of the injured person, which may afford a defence to an action brought at Common Law or under the Employers' Liability Act, both being actions founded upon negligence, may not furnish any defence to proceedings instituted under the Workmen's Compensation Act. Such a defence is not available under this last Act unless such negligence on the part of the applicant amounts to "serious and wilful misconduct," as defined by the cases, and even then is not available when death or serious and permanent disablement results from the accident.

The medical part of the work has been written mainly to assist the lawyer to understand the consequences of an accident to the part of the body alleged to have been injured, and to help him to follow the medical witnesses when they deviate slightly from the beaten track. It is not intended to instruct the medical expert in the details of his profession, but doubtless he may derive benefit by learning the special points to which counsel is likely to ask him to turn his mind. The various articles have been mainly written by physicians and surgeons attached to the teaching schools, and their names vouch for the soundness of the views which they express. The effect of accident on the various systems and parts of the body are considered in detail, and there are also articles on the effect of poisons, alcohol, anæsthetics, and electrical injuries. Each article is planned as far as possible on definite lines, and its contents are classified under identical and uniform headings. By reference to these headings the following questions can in each case be answered: What are the immediate consequences of the accident? What chance is there of disease supervening as a remote consequence of the injury? Was there any disease existing before the accident and aggravating its effects? Within what time will the man be physically cured, and when will he be fit to return to his former work, or to undertake some other employment? Is there any need for an operation, and if so, is it such an operation as a reasonable man would elect to undergo? Is there any likelihood of a recurrence of the consequences of the injury? In articles dealing with injuries technical terms have naturally to be employed, and at the commencement of each chapter these terms are explained, so that members of the legal profession can more easily follow the text. In the chapter on Accidents Occurring in the Tropics, we notice a diagram of what is stated to be the cycle of development of the malarial organism. It is only fair to state that the picture was not furnished by the author of this section.

The third section of the book is the case guide, in which is given a short epitome of nearly every case referred to in the legal section, with a number of other cases of personal injury. The object of this collection is stated by Mr. Knocker to be threefold: (1) to afford lawyers numerous instances of cases where medical points have arisen and been thrashed out, in order to assist them in advising upon or conducting similar cases; (2) to give, as far as possible, to all engaged in litigation some idea of the amount of damages which will probably be recovered; and (3) to assist medical practitioners in estimating the probable duration of incapacity after injury.

It will thus be seen that this work covers a large field, and members of the medical and legal professions who have had experience in cases under the Workmen's Compensation Act will readily appreciate the great value of such a book. We heartily congratulate Mr. Knocker on the success of his editorial duties and can strongly recommend the work to members of the two professions for whom it is intended. It is printed in clear type on good paper. The headlines are well arranged and the numerous illustrations add to the value of the written descriptions.

The Prescribing of Spectacles. By ARCHIBALD STANLEY PERCIVAL, M.A., M.B., B.C. Cantab., Senior Surgeon to the Northumberland and Durham Eye Infirmary. Bristol: John Wright and Sons, Limited. 1910. Pp. 159. Price 5*s.* 6*d.* net.

WE fear that the average student of ophthalmology, if he takes up this book, will view its pages, studded with mathematical formulæ, with amazement and such profound consciousness of his own shortcomings that he will lay it down in despair. Be it said at once that that is the student's fault, and not the author's. In the ideal training of an ophthalmologist he will have to take a serious course of mathematical optics, geometrical and analytical, theoretical and applied. But that day is not yet, and few students have both the knowledge and the energy to grapple with the problem exhaustively. For such as have the courage and enthusiasm no better introduction to the algebraical exposition of the subject can be found in the English language. Perhaps it would have been kinder to have tempered the wind to the shorn lamb and made freer use of geometrical explanations and proofs, but much of the subject matter of this book has been treated thus in lucid style by Dr. Maddox. Anyone who masters Maddox's Ocular Muscles and this book will have laid an excellent foundation, and he will find that his labour has not been spent in vain. Instead of rule-of-thumb methods only too commonly in vogue he will be armed with precise knowledge, which is the surest weapon in the battle for success. The book treats of accommodation, static refraction, and faulty tendencies and deviations of the ocular muscles. An optical section, culled largely from the author's treatise on optics, deals mathematically with the eye as an optical instrument, the tilting of lenses, two cylinders with axes asymmetrical, periscopic lenses, prismospheres, and so on. We cordially recommend the book and hope that it may be more widely studied than we fear is likely to be the case.

Physical Diagnosis. By RICHARD C. CABOT, M.D., Assistant Professor of Medicine in Harvard University. Fourth edition, revised and enlarged. With 5 plates and 240 figures in the text. London: Baillière, Tindall, and Cox. 1910. Pp. 579. Price 15*s.* net.

THE proper physical examination of cases and the correct interpretation of the signs elicited are matters of great importance in regard to diagnosis. They are also essentials in the proper equipment of the practitioner which can only be acquired by systematic examination of cases in the wards or out-patient department. A practical handbook on these subjects, from which the student can learn the proper methods of physical examination and be warned against errors, fallacies, and inaccuracies, is therefore likely to be of special value. Dr. Cabot's book is well adapted for such a purpose: it is of convenient size, it is practical, and also eclectic, since only those methods are described which the author has practical experience of, and no mention is made of those which he believes to be useless. It is this personal selection of methods in place of an ill-digested presentation of every method which gives this book its special character, and doubtless accounts for the appearance of four editions in the space of five years.

After the discussion of certain data relating to the body as a whole, including considerations of weight and temperature, the regional examination of the body is proceeded with and the various organs and systems are dealt with in order. The methods of examination appropriate to each are described, the information afforded is clearly stated, and the differential diagnostic value of each sign is worked out. Where possible tabulated lists of conditions giving rise to certain signs are attached to each section, and these constitute a valuable feature of the book. The physical examination of the

respiratory and cardio-vascular systems is described at considerable length. The methods of inspection, palpation, percussion, and auscultation are admirably worked out. The directions for the proper percussion of the chest and heart and for the choice and use of the stethoscope might with advantage be studied by all students on starting their clinical medical work, though we notice that Dr. Cabot has little or nothing to say of the rigid wooden stethoscope, which certainly has its uses. The individual pulmonary lesions and the various forms of cardiac disease are carefully and fully described, together with their differential diagnosis and the variations in the physical signs found in association with them. The essential features of blood examinations are given, and directions afforded for counting corpuscles, preparing and staining films, and for the interpretation of the results obtained. The examination of exudates and transudates and the recognition of parasites and their ova are also considered. In connexion with diseases of the kidney the analysis of the urine is described, and the significance of the results obtained is discussed, but neither kidney diseases nor affections of the nervous system are dealt with as fully as are those of the lungs and heart.

Dr. Cabot obviously writes from a large practical experience, and this gives a special value to his statements. He is sometimes caustic in his disagreement with commonly repeated inaccuracies. Thus, for example, he writes: "Enlarged veins about the navel, the so-called 'caput Medusæ,' are commonly found in text-books but rarely in cirrhosis of the liver." The illustrations are numerous, but not of a very high order. Those which are diagrammatic are useful, but of those which are reproduced from photographs many leave much to be desired. They are not worthy of the book, which is a useful handbook on the subject with which it deals.

Amœbic or Tropical Dysentery: its Complications and Treatment. By W. CARNEGIE BROWN, M.D. Aberd., M.R.C.P. Lond. With illustrations. London: John Bale, Sons, and Danielsson. 1910. Pp. 271. Price 7*s.* 6*d.* net.

THIS work is intended mainly for the use of the practising medical man, and one of its principal aims is to lay down precise and comprehensive directions for the treatment of the various clinical types of amœbic dysentery. The importance of the malady and its frequency among Europeans who are called upon to reside in the tropics are now fully recognised. For some little time information on the disease has been accumulating, and Dr. Carnegie Brown now furnishes an interesting general survey of the facts and opinions which have been formulated respecting this form of tropical dysentery, as well as of other protozoan infections of the human intestine.

The book comprises 24 chapters, which deal with the subject in seven parts—viz., (1) general; (2) biological; (3) clinical; (4) pathological; (5) etiological; (6) complications and sequelæ; and (7) treatment. After a short introduction the author gives the history and literature of the disease, and then goes on to discuss its epidemiology and geographical distribution. Following this, classification and the general relations of protozoa to intestinal diseases are considered. Four chapters are devoted to the entamœbæ of the human intestinal tract, after which other infections of the human alimentary canal are dealt with. The symptoms, diagnosis, and morbid anatomy of amœbic dysentery are respectively treated of in the succeeding chapters, as is also "the case for the pathogenicity of *Entamœba histolytica*." The causes of amœbic dysentery are then described, and hepatic abscess and other sequelæ receive the attention they need. A chapter is given on the prophylaxis of the malady, after which the subject of treatment is fully considered, both of acute and chronic forms, diet, drugs, local medication, as well as surgical and other methods of treatment being each in turn discussed. Lastly, the treatment and prophylaxis of amœbic abscess of the liver are described.

The various views on the treatment of amœbic dysentery are clearly set out, but the author does not altogether share the high opinion held by McLean and others as to the value of ipecacuanha, the *radix antidysenterica*, which in the past enjoyed for so long the reputation of being almost a specific for the disease. Dr. Carnegie Brown describes it, however, as "a remedy of moderate but definite practical utility." But whether we agree or not with the author in his views on this or other parts of the subject we must admit that he sets out the various kinds of treatment clearly and well, so that the practitioner who consults the book can never feel at a loss. For the practising physician, for whom the book is intended, the work cannot fail to prove of great service. The matter is dealt with in a clear and comprehensive manner. We confidently recommend the volume to those who may be called upon to treat or prevent amœbic dysentery.

Die Gonorrhoe des Mannes und ihre Komplikationen. (*Gonorrhœa in Man and its Complications.*) Von San.-Rat. Dr. HANS WOSSIDLO. Second revised edition, with 54 illustrations in the text and 8 plates, some of which are coloured. Leipzig: Georg Thieme. Pp. 337. Price M. 12.

NOT long since gonorrhœa was looked upon as a comparatively mild disease and of much less importance on the whole than syphilis, but at present it is doubtful whether, when we consider all the harm it may do and all its complications and sequelæ, it may not be looked upon at least as severe as, if not even more serious than, syphilis, especially if Ehrlich's recently introduced treatment with "606" fulfils its promises. With this enhanced appreciation of the importance of gonorrhœa there comes naturally the necessity for the more close study of the disease in order that its treatment may be more rapid, more thorough, and more certain. The first great step in advance was the recognition of the gonococcus, for before that discovery the exact connotation of the word gonorrhœa was uncertain. Recent advances have chiefly effected a wider knowledge of the extent of the lesions produced by the disease and better directed attempts to put an end completely to it as soon as it is recognised.

Of a large number of excellent works on this subject one of the most useful and practical is that the second edition of which is now before us. Dr. Wossidlo writes with a full knowledge of his subject, and he is well acquainted with what other surgeons have done in this branch of medicine. His book is systematically arranged. Commencing with the story of the gonococcus and the methods of staining it, there follows an account of those points in the anatomy of the urethra which are important in this connexion. The various manifestations of the acute form of the disease are then described and the treatment is fully discussed. Though many methods are referred to, probably the most useful portion of these chapters is that in which the author describes his own methods of treatment. In chronic gonorrhœal urethritis insistence is laid on the value of the urethroscope for the diagnosis of the exact condition present, and a large number of coloured illustrations are given showing very graphically various urethroscopic appearances. Succeeding chapters deal with the gonorrhœal affections of the prostate and neighbouring organs, and cystitis and pyelonephritis are also described. The treatment of stricture of the urethra is fully dealt with. Although a chapter is devoted to the manifestations of the disease in other parts of the body, we think that

the importance of this subject deserves rather more than the ten pages allotted to it, but on the whole the book affords a full and clear presentation of our knowledge of gonorrhœa.

The Microscopical Examination of Foods and Drugs. By H. G. GREENISH, F.I.C., Professor of Pharmaceutics to the Pharmaceutical Society of Great Britain. With 209 illustrations. Second edition. London: J. and A. Churchill. 1910. Pp. 386. Price 12*s.* 6*d.* net.

THE first edition of this well-known work was published in 1903 and has always held the position of a standard authority on the subject with which it deals. The author has not found it needful to make much alteration in preparing this second edition, but has made some additions, the chief one being a section on the more commonly recurring adulterants of powdered foods and drugs. The title is not quite accurate; the scope of the work is confined to substances derived from the vegetable kingdom, with the exception of sheep's wool and silk, neither of which can be said to come under the headings of a food or drug. With this qualification the work is both detailed and comprehensive. Beginning with a description of the various starches, their microscopic appearances and technique of preparation are minutely described; then follow sections on hairs and textile fibres, spores and glands, woods, stems, leaves, flowers, barks, seeds and fruits, rhizomes, and roots. A special feature in the work consists in the profusion of excellent illustrations, of which there are 209, all of them admirably reproduced; they are drawn to large scale, many of them by the author himself or in conjunction with M. Eugène Collin. The last section but one is devoted to a description of the adulterants of food and drug powders, these adulterants being classified and described according to their source of origin, not according to the situations in which they are likely to be found, or grouped under the substances which they are used to adulterate. It would have been helpful to the student to have described and figured under the heading of each article of food or drug dealt with any adulterants likely to be met with in its examination. A profusion of technical terms are necessarily used, especially in reference to botanical physiology; it would have been useful to have appended a glossary, as this book will be consulted by many who are not teachers or students of botany as a science.

LIBRARY TABLE.

Conquering Consumption. By WOODS HUTCHINSON, A.M., M.D. London: Constable and Co., Limited. Boston and New York: Houghton Mifflin Company. 1910. Pp. 138. Price 4*s.* 6*d.* net.—This is another of the many books which have recently been written with the object of showing that phthisis is being slowly driven from our midst and that the fight against it is a winning though slow one, victory being more sure if the battle be fought with greater courage on the part of the public. In a series of 12 chapters Dr. Hutchinson tells his readers, who are members of the public rather than of the medical profession, something about the tubercle bacillus, how it enters, what it does, and how best to resist its activities. The natural cure for consumption, he says, is the camp, and one chapter is devoted to this subject, while another gives specifications for various structures which can be easily built for home treatment when circumstances prevent the patient from leaving his residence. In a chapter headed, Cash and Consumption, the author points out that effective treatment must be expensive, especially to the poor. "Here is where the community must step in and help," he says. "The treatment of disease, if it is to be successful, can no longer be individual—it must be social. The community must provide the means for the worker to recover from his tuberculosis. It is morally bound to do so, because in seven cases out of ten it has made him tuberculous. It can abundantly afford to do so, to escape supporting his widow and educating his orphan children." The book is a powerful appeal to the public intelligence.

The Parson's Pleasaunce. By P. H. DITCHFIELD, M.A., F.S.A., F.R.S.L., F.R.Hist.S. London: Mills and Boon, Limited. 1910. Pp. 368. Price 10*s.* 6*d.* net.—This book is an account of the recreations and pastimes of a country parson whose hobby is archæology, who loves books and gardens, and who knows how to make the most of an annual holiday. It is divided into seven chapters, containing papers, many of which have already appeared in well-known magazines, on such subjects as gardens, old gardening books, rare tomes, village life, folk lore, and travel. As might be expected, the author has many stories to tell of the working of the rustic mind, especially in matters connected with the church. We may quote two. A parish clerk explained the 13 small figures at the foot of a monument as representing the number of wives which the subject of the monument had married, and replied to a lady who expressed her astonishment as follows: "Well, yes, marm, but you see it were rather a 'obby of 'is." A farmer who was marrying his fourth wife, and to whom it had been suggested that all his wives had possessed money, replied, "Yes, sir; but what with bringing on 'em in, and carrying on 'em out, there ain't no profit." The volume is embellished with reproductions of old prints and other illustrations, and will make a companion for moments of leisure to those who like to think—and not to think too deeply.

Life and Sport of the Norfolk Broads. By OLIVER G. READY, B.A. London: T. Werner Laurie. 1910. Pp. 249. Price 7*s.* 6*d.*—"I cannot believe that any other boy ever had so happy and so interesting a childhood as myself, with the sea on one side, the dear old Broads on the other, and the kindest of friends at every turn." In illustration of this prefatory remark the author describes men, beasts, and things in the land of the Broads as they appeared to him some three decades ago. In a style at once clear and picturesque he makes the reader feel the exhilarating effect of the wind and the frost, the cheerfulness of the sun's glow, and the magic of nature. Birds, gardening, games, live-stock, boyish pranks, fishing, shooting, sailing, ratting, and rabbiting,—all are treated in a way that only experience could have dictated, and the result is a readable book and, as far as medical men are concerned, an eloquent plea for an out-door life.

Low's Handbook to the Charities of London. London: Eliot Boothroyd. 1910. Price 1*s.*—This useful handbook of 248 pages has now reached its seventy-fifth year of publication and contains in an easy form for reference all the information which the general inquirer is likely to need with regard to the charities of London. A classified table of contents shows the various institutions according to their objects, while a brief account of each charity is arranged alphabetically. The preface to the handbook this year takes the form of an interesting sketch of the history of orphanages.

The Airy Way. By GEORGE A. B. DEWAR. London: Chatto and Windus. 1910. Pp. 253. Price 6*s.* net.—The way of an eagle in the air was one of the things "too wonderful" for the writer of the Book of Proverbs, and although since his day we have made much progress in our knowledge of the dynamics of flight the complete conquest of the air has still to be achieved. The author of "The Airy Way," however, deals with the subject principally from the point of view of a lover of nature and a careful observer of the ways of flying creatures, and discusses in a pleasant manner the motions of the wings of the inhabitants of the air as they appear to the sense of sight. This sense,

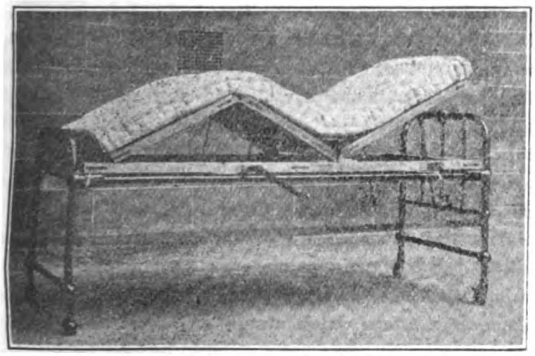
however, is very likely to be deceived, especially in the case of rapid motion like that of the wings of many birds and insects when in flight. Of this the author is aware, and he does not pretend to solve a problem towards the solution of which we are as yet in the experimental stage, but he gives us some charming descriptions of the winged feats of birds, bats, and insects which he has been watching for many years.

New Inventions.

A NEW BED-REST.

I BRING this comfortable and easily-adjusted bed-rest, especially adapted for maintaining "the Fowler" position, to the notice of the profession. My experience of several of the many bed-rests in use is either that they are difficult to manipulate or that the patient does not find them comfortable. After many trials and alterations I have found the rest which is represented in the accompanying illustration to be both comfortable to the patient and easily worked by one nurse.

The rest consists of a strong wooden frame carrying three hinged pieces for the support of the patient's back, thighs, and legs respectively. By means of a handle acting through a ball-bearing box screw the three pieces can be raised and fixed at almost any angle, so that, if desired, the patient can be brought almost into the sitting posture. Raising the thigh-piece flexes the patient's knees and prevents him slipping down the bed. No special mattress is required, for the ordinary mattress readily follows the angles of the rest, as can be seen in the figure. Enemata can be easily



administered and the bed-pan introduced by lowering the thigh-piece, while continuous saline injections can be given once the rectal tube has been inserted.

I have found the bed invaluable, not only in maintaining the Fowler position after abdominal operations, but in many other conditions. The rest can be made to fit any ordinary single bed, but should any difficulty arise it can be laid on trestles, when it acts both as bed and bed-rest. I am indebted to Mr. Woodward, clerk of works to this infirmary, for carrying out and elaborating the idea and also for the photographic representation.

PETER PATERSON, M.B., C.M.Glasg., F.R.F.P.S.Glasg.,
Glasgow. Surgeon to the Glasgow Royal Infirmary.

BRITISH MEDICAL BENEVOLENT FUND.

AT the October meeting of the committee 27 cases were considered and grants amounting to £209 made to 23 of the applicants, one case being passed over and three postponed for further inquiry. Appended is an abstract of the cases relieved:—

Widow, aged 32 years, of L.R.C.P., L.R.C.S. Edin. Since husband's death six years ago has supported herself by nursing and letting lodgings, and now asks for assistance towards the education of her two children, aged 12 and 8 years. Voted £12.

Widow, aged 50 years, of M.R.C.S. Has been incapacitated for some months owing to an accident, and is dependent on a daughter whose earnings are small. Voted £5.

Daughter, aged 68 years, of late M.R.C.S., L.S.A. No income. Is given a home in return for services, but receives no salary. Suffers from increasing deafness and general ill-health. Voted £12.

Widow, aged 46 years, of L.K.Q.C.P. Irel. Since her husband's death has maintained herself by letting lodgings and sewing, but owing to a recent illness is obliged to ask for a little help. Voted £5.

Widow, aged 34 years, of M.D. Glasg. Is quite destitute through recent death of husband and requires assistance whilst seeking suitable work. Voted £10.

L.S.A., aged 65 years. Broke down in health after the death of his wife at the end of a two years' illness and has consequently lost most of his practice and been obliged to leave his house owing to arrears of rent. Is given temporary shelter by an old patient and hopes to make a fresh start. Voted £10.

Daughter, aged 39 years, of late F.R.C.S. Has recently undergone an operation for tubercular disease of a large joint and is practically incapacitated. Relieved four times, £48. Voted £12.

Daughter, aged 40 years, of late L.R.C.P., L.R.C.S. Edin. Endeavours to support herself by nursing but finds considerable difficulty in obtaining cases. Relieved six times, £50. Voted £6.

Daughter, aged 54 years, of late M.R.C.S., L.S.A. No income and almost incapacitated by ill-health. Relieved eight times, £73. Voted £12.

Daughter, aged 61 years, of late M.R.C.S. Receives a small weekly allowance from two friends, but is unable to earn anything owing to permanent ill-health. Relieved six times, £66. Voted £12.

Daughter, aged 57 years, of late M.R.C.S. No income; supports herself by letting rooms and knitting. Health delicate. Relieved six times, £72. Voted £12.

Widow, aged 43 years, of L.R.C.P., L.R.C.S. Irel. Since husband's death has endeavoured to support herself by taking paying guests, but has had her furniture seized for rent and now contemplates emigration to Canada. Four daughters, but none able to help and two dependent. Relieved once, £10. Voted £2, and application to be further considered next month.

Daughter, aged 47 years, of late M.D. Edin. Is a daily governess, but at present has no post. Relieved twice, £10. Voted £5.

M.D. Aberd., aged 58 years. Quite incapacitated by lateral sclerosis and dependent on pensions from charitable institutions. Two children, aged 12 and 6 years. Relieved twice, £22. Voted £6.

Widow, aged 63 years, of L.R.C.P., L.R.C.S. Edin. Only income a small pension from a city company, and unable to follow any occupation on account of severe chronic rheumatism. Relieved twice, £16. Voted £10.

Widow, aged 43 years, of L.R.C.P. Edin., M.R.C.S. Eng. Supplements the help given by a stepson only earning a small salary by letting lodgings. Relieved twice, £24. Voted £12.

Widow, aged 70 years, of M.D. St. And. No income, and family only able to give slight help. Voted £12.

Daughter, aged 55 years, of late M.R.C.S. Mentally unfit to follow any occupation, and apart from a little help from a brother is dependent on three half-sisters who all have to earn their living. Relieved six times, £61. Voted £5.

Widow, aged 70 years, of M.R.C.S. Dependent on an old age pension and a daughter, who is a governess. Relieved five times, £62. Voted £12.

Widow, aged 43 years, of M.R.C.S. who for many years held a teaching post at a medical school. Endeavours to support herself by letting lodgings. Three children, all at institutions. Relieved once, £15. Voted £10.

Wife, aged 61 years, of L.F.P.S. Glasg. who has been in bad health for three or four years but has just obtained a ship's surgeoncy. Applicant lets lodgings but cannot make sufficient for maintenance. Relieved once, £12. Voted £1 and case to be considered again after further inquiry.

Daughter, aged 75 years, of late M.R.C.S. who was a surgeon in the Scots Guards. Was well provided for but lost most of her capital through the defalcations of the family solicitor and the rest through unfortunate investments. Now dependent on an old-age pension, with occasional help from relations. Relieved once, £18. Voted £15.

Widow, aged 56 years, of L.S.A. No income, and dependent on a son earning a small weekly wage. Relieved nine times, £102. Voted £12.

WATERWORKS IN HAVANA.—*La Prensa Médica*, a new medical journal which is published monthly in Havana under the editorship of Dr. Enrique Núñez, is very strongly of opinion that the subject of the water-supply should not be allowed to fall into the hands of private speculators, but should be carried out after full consultation with the medical practitioners of the capital, who are urged to form themselves into a committee for the purpose of impressing their views on the municipal authorities.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Moine, formerly inspecting medical officer in the French Military Medical Service.—Dr. Melchior Willim of Breslau, who married in 1880 a princess of the Royal Family of Würtemburg, who was obliged to resign all her dignities before being allowed to wed a bourgeois doctor. They have a son who is an ophthalmic surgeon.—Dr. De Forest Willard, formerly professor of Orthopædic Surgery in the University of Pennsylvania, Philadelphia.—Dr. James Nevins Hyde, professor of dermatology in Rush Medical College, Chicago.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 12, 1910.

The Practitioner and the Prescription.

THE article and letters[1] which we have recently published as to the rights of property or of control which exist, or which physicians might wish to see existing, with regard to prescriptions given by them to their patients call attention to a subject of real importance. The position is that conditions prevail in connexion with the property in and control over prescriptions which are undesirable in the public interest and in that of the medical profession; that these conditions can hardly be altered except by the intervention of the legislature; and that the likelihood of any effective legislative interference is remote. The undesirable conditions are not restrained or corrected by the law of copyright in any important degree. It is conceivable, and we believe that in the past it has been either attempted or threatened, that someone obtaining possession of books containing copies made by pharmacists of prescriptions dispensed by them, might fill a volume with prescriptions arranged under what he conceived to be appropriate headings for popular sale and distribution. To prevent the bringing out of such a work with the names of the prescribing medical practitioners attached to their prescriptions might present little difficulty, but it would be otherwise if no such ground of interference existed, and if it were necessary to depend upon establishing the copyright of individual physicians in prescriptions published anonymously. If such copyright does exist its ownership would no doubt be governed by the principles indicated by Mr. WIPPELL GADD, and illustrated by him from the analogous cases of the architect's plans, the photograph, and the analytical chemist's report. Without, however, going so far as to say that a physician's prescription is in no case a subject of copyright, we are of the opinion that it would be found difficult to establish the necessary element of original invention in many.

However, the danger of appropriation and publication in such a manner as we have suggested above is remote, or not likely to occur frequently, and the real question is whether any practicable means can be devised to prevent effectively the repeated dispensing of the same prescription to an unlimited extent either to the patient himself or to the friend to whom he may choose to give it. In referring to the patient's friend we have before us what we believe to be the by no means uncommon case of the man who says to another who has been telling him of his ailments, "I believe you are suffering from just what I had six months ago; I have got Dr. Blank's prescription, and I'll lend it to you. He's a first-rate man and he cured me in a week. Take it, my dear fellow, and welcome; it will save you two guineas." We have cited here men as the offenders, but women are every whit as meanly imprudent. The practice indicated is an objectionable one from the point of view of the medical practitioner and also from that of the members of the public who are prone to try dangerous experiments upon themselves. As Mr. WIPPELL GADD puts it: "In the best interests of the patient, the use of the prescription should be limited, as the very efficiency which it may possess in the morbid condition of the person for whom it was written may render it noxious or even toxic to the same person when in a state of health, and still more so to other persons of different age, sex, or habits of life." If, however, we concede that it is a practice not affected by the law as it stands, and consider the possibility of devising some means of interference which Parliament might reasonably be expected to grant, we must bear in mind the general policy in such matters of the Government under which we live. The law does not forbid the sale of any supposed cure for any existing or imagined disease, or the giving of advice of a medical character either gratuitously or for reward by any person. The prescription which a medical man may have written for a patient suffering from some form of dyspepsia which he has carefully diagnosed, may be entirely unsuited for the ailment of some other person whom he has never seen or heard of. It is, however, not likely to do him more harm than some advertising quack's "liver pill" or "kidney purifier," which the public is free to purchase and consume in any perilous quantity, and there is, therefore, no very tangible ground for inviting the legislature to interfere with the liberty of the subject in one instance more than in the other. If, however, Parliament were ever induced to remodel the whole of the law relating to the practice of medicine, and to check for the sake of the public the practice of the quack and the advertising "remedy"-monger, then it might be possible to frame regulations which would check, if they could not prevent entirely, the misuse of prescriptions in the manner indicated.

Mr. WIPPELL GADD has suggested recourse to the disciplinary powers of the Pharmaceutical Society, which might be asked to remove from its membership, as for an act subversive of the interests of the Society, a pharmacist dispensing a prescription if in so doing he disregarded a direction written on the face of it by the prescribing physician. This plan could be adopted without any statutory change by means of a by-law which is already in existence. As an alternative it is often suggested that prescriptions should be written under a printed heading to be filled up by the medical man with dates or other particulars, these being worded so as to limit its use; and the same heading might contain a warning easy to be read and plainly worded to the effect that the prescription is written to meet the case of the individual named upon it and is not likely to prove beneficial to anyone else. The whole question, however, is one of difficulty. Its solution by means of legislative change has hitherto not appeared within the range of practical politics. But a joint committee is now

[1] See THE LANCET, Oct. 1st, pp. 1019, 1030; Oct. 15th, p. 1168; and Oct. 22nd, p. 1241.

sitting of medical men and pharmacists appointed by the British Medical Association and the British Pharmaceutical Conference respectively, for the purpose of considering the relations as regards prescribing and dispensing of the two professions, and also the traffic in secret and quack remedies. Two members of this committee are members of the English Bar, so that the questions involved will be discussed with a due appreciation of the points of law involved.

Rapidity in Operating.

THE introduction of the employment of anæsthetics into surgery had results in addition to the prevention of the feeling of pain by the patient, which was the essential object of the invention. One great by-result was the extension of the operation to parts of the body which had previously not been considered accessible. But the introduction of anæsthesia had another effect, for it led to the lengthening of operations, as the surgeon had no longer to take into consideration the infliction of pain on the patient, and the speed of operating definitely decreased. In the ancient writers on surgery there is little reference to speed in operating. CELSUS appears to have been the first writer on surgery to mention the speed of operating, and he lays stress on the importance of not being moved by pity for the patient's pain to hurry the operation, and doubtless he meant that the due carrying out of the work required is of more importance than mere speed. AMBROISE PARÉ expressed himself as in favour of rapid surgery, but only when joined with experience. HEISTER in the seventeenth century claimed that the operator should be rapid but should not hurry. MORAND in 1772 urged that the phrase, "cito, tuto, et jucunde," should apply not to medicine only but to surgery also.

In the 50 years preceding the introduction of anæsthesia there was a tendency to increase the rapidity with which operations were performed, and in the hands of a few surgeons, especially skilful and dexterous, the rapidity with which an operation, even a major operation, could be performed was marvellous. Perhaps there was none who surpassed ROBERT LISTON in this respect, and when he performed in 1846 the first operation in this country under anæsthesia he amputated a thigh in less than two minutes from the commencement to the finish of the operation, for he did not expect much from the hitherto untried anæsthetic. The natural tendency, when the fear of causing pain to the patient was no longer present to incite the surgeon to rapidity, was to prolong the operation, and there has been a proneness since the introduction of anæsthetics rather to despise the rapidity with which the surgeons of a past generation operated. This feeling may go too far. There may have been a tendency at one time for surgeons to pride themselves on rapidity and to a certain extent to disregard the effect on the patient, but there can be little doubt that the tendency of the present day is to err on the other side. Many surgeons are far too slow at operations. They devote an unnecessary amount of time to small unimportant details, so that the duration of the operation may be twice that which was really needed, and the patient suffers. When the older surgeons performed their operations with lightning celerity they were thinking mainly of the feelings of the patient, but the rapidity with which the operation was done had another and even more important beneficial effect. The duration of the shock to the patient was greatly decreased. Nowadays, when the patient is under the influence of an anæsthetic, that portion of the shock which was directly due to the damage to the sensorium caused by painful impressions has been abolished, but the shock which is independent of sensation remains, and much of this is directly proportional to the duration of the operation. Even at the present time speed in performing an operation is no unimportant factor in the result. In so many cases the success or failure of the operation, its termination in the life or the death of the patient, rests on a very narrow edge, and small influences may precipitate the result on one side or the other. We have no doubt that lives may be, and are, lost by unnecessary dawdling during the operation. Even the prolongation of the anæsthesia is in itself productive of harm, and may help, in its turn, towards an unfavourable result.

We have quoted some of the references here given from an interesting article by Dr. R. T. MORRIS of New York, in "The Fourth Era in Surgery," in which he advocates strongly the need for rapid operation, and his earnest advocacy is, we think, needed at the present time. Speed is not everything. Accuracy is essential, and the operation must accomplish what it is intended to do. If a tumour and its adnexa are to be removed, removed they must be. If a limb has to be amputated, that which is necessary must be done, but much time may be wasted in unnecessarily doing more than requires to be done. All prolongation of an operation, even though it may be only measured by minutes, is an unnecessary prolongation, and though it may not lead to a fatal event its influence must be harmful. Safety lies in so adjusting the speed and the accuracy of an operation that neither is sacrificed. Much of the shock produced by an operation is beyond our control, but much rests within our hands, and that portion of the shock which is directly due to the length of the operation is that which it is in our power especially to minimise.

The Story of Pharmacy.

MODERN medicine and research are so fruitful, complicated and engrossing that medical men have on the whole little time for studying the records of the past, and the subject of the history of medicine and her allied sciences has been much neglected. But of late years a great stimulus has been given to the study of medical history by the foundation of the Fitz Patrick Lectures of the Royal College of Physicians of London, as those must feel who are reading in our columns the erudite and distinguished discourses of Sir CLIFFORD ALLBUTT. In addition to the Fitz Patrick Lectures, which have been delivered in previous years by Dr. J. F. PAYNE, Dr. NORMAN MOORE, and Dr. LEONARD GUTHRIE, we have seen produced recently such papers and essays as those of Dr. GUTHRIE on the Medical History of John Evelyn, of Mr. D'ARCY POWER on the Medical History of Pepys' Diary, together with his scholarly edition of John Arderne, and of Dr. RAYMOND CRAWFURD on The Last Days of Charles II. There are also various memoirs by the Regius professors

of medicine at the two Universities of Oxford and Cambridge, such as Professor OSLER'S papers on LINACRE, SERVETUS, and Sir THOMAS BROWNE, and those of Sir CLIFFORD ALLBUTT on Medicine and Mediæval Thought, to name only a few. Nor must we forget Dr. R. O. MOON'S interesting little book on the Relation of Philosophy to Medicine. All this work, and we make no attempt to compile a comprehensive catalogue of it, has begun to familiarise medical men with medical history, and into the category of such books fall the valuable volumes on pharmacy[1] by Mr. A. C. WOOTTON, who died before his work made its appearance. The proofs were revised for publication by his friend Mr. PETER MCEWAN, the editor of the *Chemist and Druggist*. The book, whose title, "Chronicles of Pharmacy," is, as the author acknowledges in his preface, somewhat misleading, was originally intended "to trace back to their authors the formulas of the most popular of our medicines, and to recall those which have lost their reputation. ..... But I have not succeeded in this design." Instead, however, we have a book full of learning, of the results of laborious research, of out-of-the-way knowledge, and of facts bearing upon a universally diffused aspect of human nature, in which incredulity and trustfulness are singularly mingled.

From the dawn of history the universal desire of the sick has been to "take medicine." And medicine, it should be remembered, does not in its strictly etymological meaning imply simply a drug or an application, but any form of treatment applied or supplied by the medicine man—i.e., the wise man or he who knows. The Latin words, *mederi*, *medicus*, *medicina*, go back to a root meaning "wisdom," and the same root appears in Medea, the witch or the wise woman. The Greek word from which our word pharmacy is derived—namely, *φάρμακον*—means a charm or a counter charm, and is etymologically connected with a Lithuanian word, meaning "to sing," like the Greek *ἐπαοιδή*. The earliest method of treatment, whether for good or evil, was a song, such as the well-known example in the Odyssey, XIX., 457, where the blood from ODYSSEUS' wound was stayed by an *ἐπαοιδή*; and the power of music to charm away physical ill is a belief to this day among primitive peoples. The knowledge of drugs and medicinal herbs was probably acquired much later in the history of the human race than when medicine consisted chiefly in magic. As to how it was first obtained it is useless to speculate, but once the knowledge had been acquired that certain plants and herbs possessed certain properties the beginnings of pharmacy were at hand. The extraordinary collection of animal remedies in which our ancestors delighted most likely arose from the doctrine of similars. Thus, the flesh of a lion made the eater brave; the fox was a swift animal, therefore its lungs were good for diseases of the lungs, and so on. But in some of the prescriptions there was a certain amount of sense and sound physiology, accidental though this may have been. Thus, a favourite mediæval treatment for dropsy was for the patient to drink his own urine, and it is not so many years ago that urea was introduced as a diuretic. The essence of urine, which Mr. WOOTTON quotes Madame DE SEVIGNÉ as taking, probably owed its virtues to ammonia salts. With all the changes in medicine and pharmacy, the names of some preparations have remained practically the same, for we still use the terms cathartic, trochiscus, cataplasma, and emplastrum, although such names as hiera, arteriaca, and tiriaca are practically obsolete. ISIDORUS HISPALENSIS, a seventh century encyclopædist, gives an account of medical preparations as existing in his time and why they were called by varying names. The passage is in the fourth book of his "Liber Etymologiarum." A large number of pharmaceutical preparations formerly began with the word "dia," which has survived to this day in the term diachylon. "Dia" meant from, or of, and ISIDORE gives examples such as "diaspermaton," which is so called because it is made from seeds. As time went on it came to be considered that the value of a preparation consisted chiefly in the number and variety of the drugs which it contained, and down to 1746 the Four Officinal Capitals were still recognised: they were Mithridatium, Venice Treacle, Philonium, and Diascoridium, which contained upwards of a hundred ingredients. After reading of such amazing prescriptions it is with satisfaction that we learn they are now represented by pulvis catechu compositus, which, however shorn of dignity, may still compare in value with its predecessors.

No one in reading these records of the past, to which we have just made completely desultory reference, can fail to be struck by the complicated composition of ancient remedies, a complication which naturally went hand in hand with the idea that medicine was a mystery which should not be communicated but to the initiated. Nowadays the tendency is all the other way. The simplification of pharmacy and the mass of "elegant" and easily-taken pharmaceutical preparations has certainly been no small factor in the fashion of self-medication, and the most powerful drugs can be and are daily bought in open market by the public, who drug themselves and their friends with a sublime disregard for any untoward circumstances which may ensue. That the medical profession should be a loser pecuniarily by this custom is at least one of the evils arising from the practice. It is also open to question whether the tendency in modern prescribing to set aside the canons of the older method regarding adjuvants, correctives, and the like can be altogether approved. Polypharmacy is an abomination, but it is a fact that a judicious combination of drugs often acts far better than any individual drug employed by itself. Dover's powder, Griffith's mixture, Gregory's powder, and black draught are examples of old-fashioned pharmacy which have held their ground against all adversaries. A study of Mr. WOOTTON'S book will remind the thoughtful reader that if there was much in the practice of our ancestors to be avoided, there was also much to admire.

[1] Chronicles of Pharmacy. By A. C. Wootton. London: Macmillan and Co., Limited. 1910. Two vols. Pp. 428. Price 21s. net.

THE Richard Middlemore Lecture for 1910 will be delivered at the Birmingham and Midland Eye Hospital on Thursday, Dec. 1st, at 4 P.M., by Mr. Sydney Stephenson, ophthalmic surgeon to the Queen's Hospital for Children, London, who has taken as his subject, "The Consequences of Eye-Strain." All qualified members of the medical profession are invited to be present.

Annotations.

"Ne quid nimis."

THE FIFTH INTERNATIONAL CONGRESS FOR THE BLIND.

THERE are many scientific congresses held which supply a pretext for a journey, and of all such congresses it would be difficult to find one with more inducements to medical men than an international congress to consider the amelioration of the lot of the blind. The Fifth International Congress with this object is to meet at Cairo from Feb. 20th to 25th, 1911, under the distinguished patronage of His Highness the Khedive. The business sittings will be held at the University buildings under the presidency of the Minister of Foreign Affairs, but the Congress will be inaugurated by the Khedive in person. There are eight questions inscribed for discussion, namely: 1. When can a person be considered as blind? 2. How to prevent the spread of ophthalmia? 3. Has Esperanto been of any use as a universal language for the blind? 4. What is the best method applicable to all languages of teaching stenography to the blind? 5. What are the best trades and professions for the blind? 6. What are the best games and bodily exercises for blind school children? 7. Can the Braille method be improved? 8. Could the blind be employed in telegraph and telephone exchanges? These questions will be discussed in the mornings, and only short speeches are to be allowed. Reports must be sent in by Dec. 1st, so that they may be printed before the Congress meets. In the afternoons the members of the Congress will be conducted to the Museum of Egyptian Antiquities, to the mosques, to the Delta barrage, to the Arabic Museum, and the mosque of El-Azhar. There will be an excursion to the Pyramids of Giza and a lunch and a banquet. The entrance fee is the usual one of 20 francs, or 16*s*., and intending members should write to the secretary-general of the Congress at the University buildings. The card of membership entitles the bearer to a 50 per cent. reduction of the fare on the Egyptian Government railways, free admission to museums, monuments, and reduced rates at some hotels and on some of the steamships from Europe to Egypt. This then is an excellent opportunity of seeing Egypt under economical conditions, and at the same time of rendering some service to the blind. Indeed, those who are seeking a pretext to avoid the rigours of a northern winter will be tempted to persuade themselves that they have taken a special and life-long interest in the conditions of the blind. Egypt, of all countries, suffers most from eye diseases and blindness, therefore a visit to that country will create interest in the question among those who had not thought much about it before. We therefore wish the Congress every success, both as to the outcome of its deliberations for the amelioration of the conditions of the blind and as to the enjoyment of its members.

SCENT IN TOBACCO.

WE may well inquire on what ground the great bulk of the tobacco smoked by the people is scented. Foreign flavours are present sometimes in nauseating excess and the fragrance of pure honest tobacco is to most smokers a mere memory. We are quite prepared to be told that the public like, or even prefer, a scented tobacco, and therefore the trade must be ready to meet the peculiarities of its customers. If that is the case, the palate of the public, for some reason or other, must have gone astray, which is a pity, since a vitiated taste quickly invites bad trade practices. It is pretty certain, at any rate, that if the real demand of the smoker is in favour of a highly scented tobacco it matters very little what the quality of the tobacco is. He does not seek the pleasing qualities of the tobacco itself, unadulterated, unoiled, unscented: he is satisfied with an added scent which is not due to tobacco at all. To him tobacco merely serves the rôle of a smouldering vehicle, his choice of a brand being based upon a scent which is foreign and artificial. Depraved taste may be traced, we think, to the action of the trade in the first instance, and to the meek and weak attitude of its patrons. The matter is one of some importance, because a consideration of it naturally suggests the possibility of foreign materials in tobacco which may give additional risks to the smoking habit. The word adulteration may be objected to, but it is difficult to avoid its use in view of the fact that large quantities of foreign scents, besides oils, glycerine, formaldehyde, or other preservatives, are added to tobacco. Our view is that it would be better if the tobacco manufacturer kept no account with the drysalter and chemist.

PROGRESS IN KOREA.

UNTIL the last few years but little was generally known about the "Hermit Kingdom" of Korea, called by its inhabitants the land of the "Morning Calm." Since the conclusion of the Russo-Japanese war the vigour and activity of the Japanese nation have been manifested in many ways, but perhaps in none more striking or more beneficial than in its relations with Korea. For many years previously Japan had been trying to induce her neighbour to adopt modern methods of administration, and in 1905 a convention was concluded by which a Japanese Resident General was stationed in Korea, with practically complete control of the administration of the country, Japan undertaking to maintain the welfare and dignity of the Korean Imperial family. Since that date the progress of the country has been remarkable. In place of an almost universal system of corruption in the central and local governments, with complete stagnation as regards productive industries, improvement of means of communication, education, and sanitation, we now find a complete change. The policy of the "open door" has been adopted; the mineral resources of the country are being developed with the aid of foreign capital; railways, roads, and bridges have been constructed; a postal, telegraph, and even telephone system installed, including also a complete system of post-office savings banks. Nor has the public health of the country been neglected. Within a few months of taking over the internal affairs of the country vaccination was introduced, some 50 Japanese physicians being distributed through the various provinces to carry this out; the number of small-pox cases has decreased, but it is too soon yet to form any accurate estimate of the improvement that has been effected. During the last year a large distribution of vaccine prepared at the Government laboratory has been made; and female vaccinators are being trained to meet the objection on the part of Korean women to contact with strangers of the male sex. General sanitation in Korea had been absent. There was no system of refuse disposal, and well waters were everywhere polluted. Municipal organisations were set on foot, that at Seoul, the capital, started in 1907, being a joint undertaking of the municipality and the Japanese settlement. It seems that already a considerable improvement has taken place, the city presenting quite a new aspect. In the same year several charity hospitals were established. A Government hospital and medical school on a comparatively large scale have been inaugurated at Seoul, the most healthy location on Madzusan Hill having been selected for its site; provision has been

made for gynæcological cases, diseases of the eye, ear, and throat, in addition to ordinary hospital wards; also isolation accommodation has been provided for infectious diseases; a charge is made to those who can afford to pay, and free treatment is given to those who cannot. A medical school is attached, the staff consisting of Japanese and Korean medical men and one American physician. At the present time waterworks are in course of construction for Chemulpo, the port of Seoul, and at Fusan, on Broughton Strait, the principal port of communication with Japan. These undertakings are expected to reach completion at the end of the present year. Perhaps no more striking example of material improvement on scientific lines, skilfully designed and energetically carried out, has ever been afforded, even in the history of British or American enterprise. We are justified in hoping that the state of Korea will now in great measure be free from the devastating plagues that are the common lot of many oriental populations at periodic intervals. It is no exaggeration to say that civilisation owes a debt of gratitude to the Japanese nation for using their strength not tyrannously, but for the good of the people committed to their charge.

TOXICOLOGICAL TESTS FOR COLCHICINE.

THE small amounts of organic poisons recoverable from bodies after death in some cases of poisoning render the tests for these substances and their delicacy matters of very great importance in medico-legal practice. Some vegetable poisons, such as strychnine, veratrine, atropine, and physostigmine, are more or less satisfactorily recognisable by chemical tests alone, whereas for others, such as curarin, muscarin, nicotine, aconitine, abrin, and ricin, chemical reactions are not by themselves sufficiently characteristic for small quantities, and it is necessary to have recourse to biological tests. For the chemical tests a larger quantity and a greater degree of purity are necessary than is the case for many biological reactions. Colchicine is a substance with very definite toxic properties, and it is therefore of importance to study it from a toxicological point of view. It gives certain chemical tests, which are characteristic if a sufficient quantity of the substance is available. An interesting paper on this subject appears in the *Archiv für Experimentelle Pathologie und Pharmakologie*, Vol. LXIII., p. 356, by Dr. Hermann Fühner. He finds that colchicine occurs in varying quantities in different parts of the colchicum plant. It is most abundant in the seeds, where it is present in quantities varying from 0·2 to 0·4 per cent. The corm contains from 0·08 to 0.2 per cent., and the flowers and leaves from 0·01 to 0·03 per cent. In regard to the toxicity of colchicine 3 milligrammes in a single dose have proved fatal in man. Herbivora are more resistant to its action than other animals. Jacoby gives the toxic doses by subcutaneous injection of crystallised colchicine (containing 30 per cent. of chloroform) as 7 milligrammes for rabbits, 1 milligramme for dogs, and ½ to 1 milligramme for cats per kilo of body weight in each case. Frogs show an extraordinary resistance, since they can bear as much as 60 to 100 milligrammes. This is, however, only true of pure colchicine. Commercial colchicine often contains a substance called oxy-dicolchicine, the result of the action of light and air upon it, and frogs are more susceptible to this substance. Certain observations by Obolonski and Ogier show that colchicine resists for several months the putrefactive processes occurring in dead bodies containing it, a point of considerable importance medico-legally. It is, however, stated that certain putrefactive products may show chemical colour reactions similar to those given by colchicine. Dr. Fühner therefore maintains that it is necessary to apply biological tests as well as chemical in order to demonstrate conclusively the presence of small quantities of this substance. The most important colour reaction of colchicine is that given with concentrated nitric acid; violet and green colours appear, then gradually fade and pass into yellow. This yellow solution with an excess of caustic potash gives a cherry- or orange-red. Dr. Fühner describes a modification of this reaction which is sensitive for quantities between 1-100 and 2-100 of a milligramme. The solution containing colchicine is evaporated to dryness in a glass and the residue is dissolved in three drops of concentrated sulphuric acid, which gives a yellow solution. A glass rod which has been dipped in concentrated nitric acid is drawn through this solution, when the characteristic violet colour appears. If only small quantities of colchicine are present the colour soon fades completely. Caustic soda or potash is then added, and at the junction of the two fluids a cherry-red colour appears. Zeisel's ferric chloride test was found to be less delicate than this; however, a modification employed by Dr. Fühner gave satisfactory results, but its limit of sensitiveness lay between 2 and 5 milligrammes. The method consists in heating from 3 to 5 cubic centimetres of the solution to be tested with five drops of dilute sulphuric acid in a hot-water bath for half an hour, and then adding ferric chloride solution, drop by drop, so long as the green colour which results becomes darker. The fluid is then cooled and a third of its volume of chloroform is added. On shaking, the chloroform becomes coloured from yellow to garnet-red, according to the amount of colchicine present. After injection of colchicine into cats symptoms do not appear until several hours, and death does not occur until at least six or seven hours after injection. For the small quantities recoverable from bodies after death Dr. Fühner suggests the use of white mice, the fatal dose for animals between 15 and 20 grammes weight being between 1/50 and ½ a milligramme. The symptoms of poisoning by colchicine consist in sickness and diarrhœa, death resulting from respiratory failure. Dr. Fühner also found that the susceptibility of frogs to this poison was much increased by raising the temperature at which they were kept.

QUARANTINE AT MALTA.

FROM statements published recently in the *Malta Herald* it appears that serious complaint has been made against the Government for conniving at evasion of the existing quarantine regulations by certain officials and privileged persons. Special prominence is given to the case of an English military officer and his wife who travelled from England through Italy by rail to Naples, where they took ship for Malta. On arrival at their destination they at once received free *pratique*, although their fellow passengers, including at least one Maltese officer, had to comply strictly with the five days' quarantine imposed on all arrivals from Naples. The Maltese opinion is that this officer and his wife, by evading the forced detention for the prescribed period, exposed the inhabitants of the island to the serious risk of having cholera introduced among them. In this view, however, we are unable to concur, for we do not believe that cholera can be kept out of Malta or anywhere else by quarantine. It is to perfect sanitation that we must look, so that if the germs of the disease are conveyed to the island they may not find a soil on which to multiply and produce their epidemic crop. Five days' detention, for instance, will not prevent a chronic carrier of cholera from bringing with him the microbes of the disease into Malta, but proper sanitation will prevent his discharges from contaminating water and food-supplies. Hence we believe that the modern method of medical inspection of fresh arrivals from infected ports, together with the taking of names and addresses to which the passengers can be

followed, and their health supervised if necessary by the local authority during the necessary period, will meet all requirements—so long, that is, as the sanitary circumstances of the locality are satisfactory. We are well aware that these precautions just mentioned, which have been now adopted by most of the Great Powers, are characterised in Malta as "derisory measures" in which no confidence can be placed. Apparently it is still believed by the Maltese people that cholera is carried about the person or by the clothing, and that detention, with all its discomforts on board ship or in a lazarette, followed by fumigations of wearing apparel, is absolutely necessary to prevent the spread of the disease. The Malta Government, it may be mentioned, when asked for its explanation of the reported evasion of the quarantine regulations by the officer and his wife, replied through the Acting Lieutenant-Governor that it reserved to itself the right to deal with such cases on their merits according to circumstances, and that the presence of the officer in question was urgently needed in connexion with his military duties. It cannot be denied that in some few instances medical inspection and the taking of names and addresses may not suffice, but for these cases special provision can be made. Dirty deck-passengers, for example, or panic-stricken pauper refugees fleeing from a cholera-infected district, might require special attention before being allowed to land on the island. Such persons probably would not be in a position to furnish trustworthy addresses to which they could be traced or where the local authorities could keep them under surveillance. For these, therefore, stricter measures may be needed, and for them some detention might be desirable. But for military officers, public officials, professional men, well-known residents, or visitors of responsible position, proceeding to addresses that are well known to the authorities, more particularly when such fresh arrivals have travelled first-class and have merely passed *en route* through an infected port, having had no chance of contracting infection, we regard five days' detention as not only wholly unnecessary, but also as vexatious and valueless. We trust, however, that the day is not far distant when the Maltese people, who have hitherto been too prone to panic, will see the folly of their present ways; and we hope that they will seek salvation in sanitation, forsaking finally the exploded and obsolete methods of mediæval quarantine.

TREATMENT OF HÆMORRHAGE IN THE NEW-BORN BY DIRECT TRANSFUSION.

IN the *Boston Medical and Surgical Journal* of Sept. 15th, Dr. F. S. Newell has reported a remarkable case in which hæmorrhage in the new-born was treated by direct transfusion. A female infant, the second child of healthy parents, appeared to be normal for the first 24 hours after birth. She then vomited half an ounce of bright-red blood. Three hours later, at 8.30 P.M., she vomited about 2 ounces of blood. Two other hæmorrhages occurred, and at 9.30 a large motion of meconium mixed with blood was passed. She was pale, but apparently in good condition, the pulse ranging from 130 to 135. It was thought probable that the hæmorrhages would not stop spontaneously and that whatever was to be done had better be done while the child was in good condition. It was decided to perform direct transfusion from the child's father, which was done by Dr. J. C. Hubbard. Owing to the small size of the child's veins the operation was difficult. The left popliteal vein was first exposed, but was found to be too small to permit union with the father's radial artery. The internal saphenous vein was then dissected out, and with considerable difficulty union was secured by the Elsberg cannula. The connexion was allowed to persist for 25 minutes, and the wounds were sutured and sterile dressings were applied. During the transfusion the child passed three large motions containing old and bright-red blood, but after this no further hæmorrhage occurred. The operation was so difficult that it took two hours before connexion of the vessels was established. After the operation the child's state much improved, the colour and the pulse being better. On the following day she seemed weak and listless, but otherwise was in a satisfactory condition; the temperature was 103° F. and the pulse 120. On the third day after the operation the temperature fell to normal. As the mother had no milk the child was fed on whey, which was gradually increased in strength until a full-strength milk-whey mixture was given at the end of three weeks. She was discharged from the hospital five weeks after delivery, weighing 9 pounds. Dr. Newell emphasises two points—the great difficulty of performing transfusion in the new-born on account of the small size of the vessels, and the prompt checking of the hæmorrhage as soon as the effect of the father's blood was noticeable. It was extremely difficult to keep the wound in the groin from being constantly contaminated by urine and fæces. Recorded cases seem to show that early cases of hæmorrhage in the new-born can be successfully treated by transfusion. On the other hand, the results have been unfavourable in cases of late hæmorrhage—i.e., in those occurring after the first week. This points to a pathological difference between the two conditions, and suggests that the late cases may be due to some septic process, in which case transfusion cannot be expected to be successful. The difficulty of the operation is such that it should be undertaken only by an expert surgeon.

"PERSECUTION MANIA."

A FREQUENT correspondent writes from Rome:—Only the pen that described for us Quasimodo's behaviour from the height of that basilica towards the tumultuous crowd below could do justice to a recent "sensation" in Rome—the siege of a madman in his own house, from which, for well-nigh 48 hours he defied the police, the fire brigade, and even the military to dislodge him, keeping up an intermittent discharge of musketry on the besiegers and the crowd that thronged the street, till at length, the water-hose having been plied in vain, he was "fumigated" into impotence like a wild beast in its cage, and consigned, in a strait waistcoat, to the "manicomio" of the Santo Spirito! Francesco Moncada, aged 45 years, a pleader of some distinction at the Roman bar, was a fair specimen of the Sicilian physically, intellectually, and morally, with the characteristics "good and not so good" of his fellow-islanders. With his wife and three children he had lived for some years in the Via Ottaviano, but of late his professional practice began to dwindle, to the manifest discomfort of his family and the depression of his spirits. On Sunday, Oct. 9th, he betrayed the first symptoms of the "mind diseased," announcing that he had been the prime agent in bringing about the fall of the Portuguese monarchy and that, from one minute to another, he was expecting the telegram which was to proclaim him President of the Republic. As the time wore on, he protested that there was a plot to get rid of him by poison, in dread of which he kept the house, wandering from room to room, armed with rifle, revolver, and "bastone animato" (sword stick). His wife and children tried to calm him, but in vain. He became furious and ordered them out of the house, suiting the action to the word. This was on Monday evening (the 10th). Madame Moncada had by this time informed the head of the Pubblica Sicurezza, who happened to be a friend of the family, and who tried by addressing him through the keyhole to bring him to reason,

but without effect. On the following day Signor Moncada pushed a letter under the door, which, on being picked up on the landing, was found to be addressed to the head of the Pubblica Sicurezza, and to convey among a tissue of rambling phrases the announcement that he had been condemned to death and that his life was threatened by the "rabble." The news by this time had spread far and wide that a dangerous lunatic had barricaded himself in his own house and the inevitable crowd was thronging the street below when suddenly it scattered in all directions to the cry, "il pazzo spara" (the madman is firing), women fainting, and the shops hastily shutting up as the "besieged resident" continued to discharge his rifle. Among the fallen was picked up a woman with a shot through the right temple, from which she died shortly after removal to the hospital, while two other women were hit and seriously hurt, and a carabineer had his coat perforated by a bullet. The fire brigade after perforating an upper floor of the tenement at various points pumped in jets of water which gradually made upon the madman, but still he was able to discharge rifle and revolver from the window, which he continued to occupy all night. Evidently the water did not incommode him, and so another plan was adopted. Strong fumes of sulphur from various holes in the roof were projected into the apartment, till through a chink in the wall he was seen to become stupefied, recovering himself, however, from time to time so as to be still "dangerous to be approached," as was found by two of the police who made their way into the room and barely escaped a couple of shots. Before he had time to reload, however, they threw themselves upon him, wrested his rifle from him, and after a desperate struggle overpowered and secured him. On appearing in the Via Ottaviano with their captive they were loudly cheered by the immense throng of people, through whom they passed with some difficulty, in a motor-car to the Santo Spirito. There, under treatment, the man has since come to himself, and on being told the incidents of the 48 hours of siege was filled with astonishment, protesting that he had "never fired a shot"! In fact, his mind was a *tabula rasa* for all that terrible time. Later in the day it was found advisable to keep him still in the "camicia di forza" (strait waistcoat) and to place him in a ward for the "furiosi" (violent patients), previously to removing him for further treatment to the Asylo Provinciale. No such case has been recorded in Rome since 1870, and that on a less tragic scale; the case, to wit, of a Papal Zouave who, under a similar hallucination, barricaded himself in a room in the barracks of the Campo dei Fiori from which he was not extricated till he had fired 50 rifle shots and wounded, though not fatally, many of his comrades.

VIEWS UPON HÆMOGLOBINURIA.

THE conditions in which hæmoglobin is passed in the urine have for many years attracted considerable attention. The pathogenesis especially has given rise to much discussion, and many theories have been propounded to account for the destruction of the red blood corpuscles. The disease is described briefly in text-books on general medicine, and numerous contributions on the subject are found scattered through medical literature. We have received a small work with the title "Hæmoglobinuria," by Dr. A. E. L. Charpentier,[1] in which an excellent *résumé* of the present knowledge in reference to the disease is given. Dr. Charpentier bases his observations on four cases of paroxysmal hæmoglobinuria which were under his own care, and in addition he has made a thorough search for the experience and conclusions of other writers as given in various medical publications. He adds to his book a comprehensive bibliography which should be of assistance to those who are interested in the many aspects of this morbid condition. After a careful review of the principal investigations which have been made more particularly into the symptomatology and pathogenesis of paroxysmal hæmoglobinuria, Dr. Charpentier gives a summary of the conclusions at which he has arrived as follows. He contends that a paroxysm of hæmoglobinuria occurs in a man whose blood is altered by syphilis, malaria, or some other condition, causing his blood to contain a potential toxin. The toxin in the serum consists of two parts—an intermediary body and complement, which only becomes active at a lowered temperature and subsequent body heat. Dr. Charpentier then remarks that some authors maintain that in these patients the circulation is slower than normal, and they have greater difficulty in keeping up the surface warmth; hence, on exposure to cold, the blood in the skin capillaries becomes cooled, a certain amount of stasis also takes place, when the complement and intermediary body unite with the corpuscles, which immediately undergo a rapid phagocytosis, the hæmoglobin being set free in the vessels. He thinks it is probable that the exposure to cold of the skin also causes the arterioles to be constricted by means of the "vaso-motor arc," and at the same time it is likely that either the presence in the blood of the toxin or of the free hæmoglobin will influence the system at large by means of the hormones. If the free hæmoglobin is above a certain proportion, the symptoms of hæmoglobinuria of varying intensity are induced, including the passage of hæmoglobin through the kidneys. Dr. Charpentier then points out that in these processes an enormous number of erythrocytes are destroyed, but are very rapidly reproduced. The kidneys, in excreting the hæmoglobin, become congested by the irritation, so intensifying the symptoms. The amount of pigment and urea is largely increased by the hæmolysis, and also adds to the disturbance of the functions. Warmth and rest, he says, allow time for the kidneys to recover, and probably for an antigen to form, when the hæmoglobin is excreted and the organs resume their natural functions. This little volume contains much that is interesting upon rather an obscure and rare condition, and Dr. Charpentier has rendered a service to medical literature in collecting and arranging the material which has hitherto been so widely scattered in books and publications in many countries.

THE SANITATION OF MADEIRA.

Dr. Michael C. Grabham, author of "The Climate and Resources of Madeira," writes us the following note which will be of interest to many of our readers and their patients:—The outbreak of typhoid fever which, it may be remembered, happened during the height of last season at Madeira, subsided as mysteriously as it commenced, no fresh case having been notified since the early days of the month of March. It will therefore be reassuring to both the visitors who from now onwards crowd the hotels and villas of these mountain slopes, and to their friends at home, to know that the island is once more healthy and inviting, and moreover, that drastic improvements have been accomplished during the recent months. New drains, new kitchens, and food-storage arrangements figure prominently among the latest developments, but pre-eminently to be mentioned is an adequate supply of mountain water, drawn in iron pipes at an elevation of 3000 feet from a region far above cultivated ground and human habitations. Messrs. Reid, the principal proprietors, have also started a special dairy for the supply of milk to their hotel guests which will add to the general security against disease. It is important to add that the new Republican *régime* has been accepted locally with even less

excitement than is usually evoked by political party change, and that the claims of Madeira, long neglected, will now be pressed upon the new Executive in the international interest of the place as a health resort, whose winterless and perennially vernal climate has now been brought within three days' journey of England by the sumptuous liners of the Union Castle Company. The overflowing revenue and prosperity of Madeira are truly due to these influences, and they cannot be too sedulously fostered in the interest of Portugal. Latterly Madeira has been by no means frequented by health-seekers exclusively, but the island is becoming more and more the resort of the tired and overworked—not of the average tourist, but of those to whom complete intellectual rest is impossible at home, who desire light and sunshine, and who seek distraction in fresh interests and new environment.

COCOANUT "MILK."

NOT a few people have wondered what kind of stuff the "milk" of the cocoanut is. The inducement held out to buy the nuts or "shy" for them is generally that they are "all milky." Recent analyses, however, have dissipated the delusion that the fluid has anything in common with real milk. It contains only 4 per cent. of solids, consisting chiefly of sugars 2·8 per cent., the balance being made up of mineral matter and tartaric acid. It is interesting to record that more than half of the sugar present is mannitol, the sweet principle of manna which is sometimes found also in wine as a product of normal grape sugar. The question has been discussed as to whether it would be profitable to extract the cocoanut water for the sake of its cane sugar, but as this amounts to only $\frac{1}{10}$th per cent. the process would not be commercially successful, in spite of the water being a waste product. Even if the water contained 5 per cent. of sugar, as some specimens appear to have shown, the recovery of this amount would be unprofitable. The juice of the sugar cane yields nearly 20 per cent. of sugar.

MATERNAL INFLUENCE IN MENTAL DISORDERS.

IN the annual report of the East Sussex County Asylum Dr. F. R. P. Taylor, the medical superintendent, records, as a result of inquiries made into the family histories of patients under his charge, that in 247 of 277 direct admissions a family history was obtained, and that heredity was ascertained in 28 per cent. of the males and 43 per cent. of the females. It would be both of interest and practical importance to learn if these figures are similar to those obtaining in the statistics of other institutions. It is perhaps natural to expect that a tendency to insanity in the mother is more likely to appear in her offspring than is a tendency to insanity in the father likely to appear in his. The nervous system of the child is in part elaborated in utero in a period during which the mother herself is peculiarly liable to mental disorder, sometimes slight, sometimes serious in its manifestations, and in part during those early years when the maternal influence is paramount. If that influence, whether within or without the womb, is good it is well with the child, but if, on the other hand, it is for some reason not good the offspring, *pari passu*, is affected. The life-history of women is bound up to a far greater extent than is that of man with matters of generation. It is a common observation among physicians, and indeed amongst lay folk as well, that the menstrual flux is very frequently preceded by, accompanied with, and succeeded by peculiarities of mentality, and that therefore in many women mental equilibrium is scarcely known, and is replaced until middle life by tones of feeling, effectivity, and thought in perpetual see-saw. It is scarcely to be doubted that such states as these exercise subtle educative influences and may result in just those failures in mental balance which may subsequently dispose the offspring to mental breakdown. From another point of view it is to be remembered that certain affections seem to be transmitted through unaffected female progenitors to male offspring, and it is at least legitimate to regard it as possible that in other disorders a like tendency exists, while it would be interesting to investigate the characters of the insanities which appear to be of maternal origin and to compare them with those which appear to be of paternal origin. There can be no doubt that within a comparatively few years our generation has seen a metamorphosis of the character of the lives led by women; such a change indeed as history does not record. It is full early to pronounce on the effects which are likely to accrue, but it is plainly of vital importance that we should watch the direction of the drift of those few straws which too often are our only guides, and we should regard with satisfaction a further development of Dr. Taylor's observations.

THE TREATMENT OF TUBERCULOSIS ON THE MEDITERRANEAN COAST: HELIOTHERAPY.

AT a meeting of the Académie de Médecine of Paris on Oct. 11th M. Debove made a report on a paper by Dr. Révillet of Cannes, entitled "The Treatment of Tuberculosis in Children on the Mediterranean Coast by Sea and Sun." Though the topic may seem trite the results are so remarkable as to demand attention. They are more trustworthy than the usual "excellent results" of therapeutics, for the undue optimism which, however honest, seems inseparable from writers who are describing the results of their own methods can be excluded. Here the patients were Swiss children sent from Geneva to Cannes by a philanthropic society. Before departing and on returning they were examined by Professor d'Espine, and the results are given in an annual report. It is noteworthy that, in spite of the proximity of their own renowned mountain sanatoriums, the Swiss should prefer to send these children to the Mediterranean. Cannes possesses great advantages which has led Professor d'Espine to recommend it, but these exist almost equally all along the coast between Hyères and Vintmille. It has a sloping sandy beach protected from cold winds on the north, east, and west by mountains and open only to the south—an ideal condition for the treatment of tuberculous children by sea, air, and sun baths. The band of Swiss children arrives each year in the middle of October and remains until about the middle of June. Any who show signs of "open" tuberculosis are rejected because of the danger of contagion. At the time of arrival the sea is warm, having a temperature of about 64° F. As winter approaches the temperature falls to 46°. The children bathe daily and do not notice the fall of temperature. The sea bath is always short, lasting from one to three minutes at most. A marked cutaneous reaction always results and there has never been the least accident. The bathing is continued through the winter even during the coldest month. The greater part of the day is devoted to heliotherapy; the tuberculous part is exposed naked to the rays of the sun. Sunless days are so few in this fortunate clime that sun bathing is possible for 190 out of the 240 days of the children's sojourn. The reverse holds in mountain climates; sunny days are the exception. The effects were striking. Pale, emaciated children, many of whom were subjects of severe disease, underwent a veritable resurrection. Appetite, colour, and spirits returned. The average gain in weight was 4 kilogrammes. For superficial tuberculous glands insolation proved most efficacious; it dried up suppuration and reduced the keloid-like projections and depressions. Progress was rapid and the surface became covered with a

supple scar which assumed the colour and characters of normal skin. Old glandular sinuses, which resisted all previous treatment, rapidly closed. Of 63 children suffering from Pott's disease 27 were cured, 26 were improved, and 6 remained stationary. Four died—three from an intercurrent disease and one from exhaustion the result of prolonged suppuration complicated by amyloid kidneys. Of 94 children suffering from hip disease and "white swellings" 38 were cured and 50 were improved. Professor d'Espine found that a certain number of children suffering from hip disease were completely cured after treatment for eight months at Cannes—a result exceptional at other latitudes. The results were not less brilliant for "white swellings," in the treatment of which immobilisation was avoided. Dr. Révillet considers that rest treatment is much abused and is the cause of ankylosis and muscular atrophy. In a number of cases "spina ventosa" was rapidly cured by exposure to the sun. In tuberculous peritonitis effusion and meteorism rapidly disappeared; in 7 cases 3 patients were cured, 3 were improved, and 1 died from perforation. In 11 cases of lupus, 8 patients were cured and 3 were improved. The diseased surface was gradually exposed to the sun until a stage was reached when the treatment could be continued for the greater part of the day. Progress was rapid; nodules were effaced, crusts fell, slight desquamation was produced, and islets of white skin were formed. Finally, a smooth supple scar, never keloidal, was produced. To sum up, in 888 cases of tuberculosis positive results were obtained in 93 per cent., and cures in 52 per cent. It is to be noted that these results are not merely the statement of Dr. Révillet about his own methods, but are vouched for by Professor d'Espine. What lesson do they teach? In this country the open-air treatment of tuberculosis has become a commonplace, but we think that the value of heliotherapy, particularly of exposure of the diseased part to the sun, is not sufficiently appreciated. Though for this purpose England is inferior to the Mediterranean littoral, it should not be forgotten—and our frequent meteorological notes prove it—that we have many places on our southern shores where the daily aggregate of sunshine is considerable.

THE HISTOLOGY OF THE SCARLET FEVER RASH.

THE histological characters of the exanthem of scarlet fever form the subject of an interesting paper contributed to *Medicinische Blätter* of Oct. 22nd by Professor J. Hlava of the Bohemian Pathological Institute of Prague. He states that the most important previous observations on this subject are those of Neumann and Unna. Neumann described swelling of the cells of the rete and the formation of gaps and networks in which wandering cells were enclosed. Unna maintained that the swelling of the skin resulted from the hyperæmia of the vessels of the corium, and that the changes in the epithelial layer were but slight. Professor Hlava's observations were made upon the skin of 18 fatal cases, and also on small pieces removed *ex vivo* in seven other cases. He concludes that the chief changes occur not in the horny or granular layers of the epidermis, but in the cylindrical and prickle layers and in the corium. There is a hyperæmia associated with œdema. The œdema extends into the epithelium and may penetrate through the granular layer to form small vesicles in the horny stratum. In the epithelium small areas of softening may result from imbibition or from necrosis. These areas may involve groups of prickle cells, the disorganisation starting at the periphery of the cells and extending in towards the nuclei, which become disintegrated. The central cells of these areas of softening may show the changes to a lesser degree, the protoplasm being simply homogeneous and the nuclei pyknotic. A few polymorphonuclear leucocytes may occur in and around these softened areas, but this leucocytic invasion is at most slight. Some dilatation of the lymph channels of the papillary layer with enlargement of the endothelial cells can be seen even before the appearance of the rash, and they may contain some débris of red blood corpuscles. On the first day of the eruption mononuclear cells with a few polymorphonuclears occur around all the blood-vessels of the corium, but even by the fourth day there is very little proliferation around these vessels. No changes of any kind are discernible in the sweat or sebaceous glands. The appearances in fatal cases are somewhat different. The epithelial cells contain more pigment; hæmorrhages and connective tissue cells containing pigment are much more common in the corium, and the cell proliferation around the blood-vessels is more marked. These differences are probably referable to the hæmorrhagic character of most of the fatal cases. Professor Hlava concludes that the hyperæmia, the serous effusion, the leucocytic changes, and the later cell proliferation about the blood-vessels are in favour of the inflammatory nature of the process rather than of the view that it is a simple toxic œdema.

THE Lord Mayor has become chairman of a Mansion House committee formed to promote the raising of a fund for the erection of a new building for the Royal Society of Medicine, which already possesses a splendid site.

A POWERFUL claim has been made by the Society of Tropical Medicine and Hygiene for the endowment of the study and prevention of tropical disease as a memorial to his late Majesty King Edward VII.

THERE has been praiseworthy activity during the week in the districts where plague-infected rats have been found, but evidence of a spread of the infection has been forthcoming.

WE regret to announce the death of Professor Lancereaux, which has just occurred at the age of 80.

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of this society will be held on Nov. 16th at 8 P.M., when there will be an exhibition of specimens of British mycetozoa by Mr. A. E. Hilton.

THE NOTIFICATION OF OPHTHALMIA NEONATORUM.—The Midwives Act Committee on Nov. 8th asked the London County Council to take action with a view to the more effectual prevention of blindness or impairment of vision caused by the want of prompt and efficient medical treatment among newly born infants, and recommended the compulsory notification of all cases of ophthalmia neonatorum. So far as the practice of certified midwives was concerned, the committee stated, a method of notification already existed, as one of the rules of the Central Midwives Board required every certified midwife to advise that medical assistance should be obtained in every case of inflammation of the eyes, however slight. If the Council made the order the information obtained would enable the medical officers of the sanitary districts to make known to those concerned the opportunities available in necessitous cases. It would be found of value where the infant was taken to a hospital, where the medical practitioner perhaps would not have an opportunity of keeping the infant under treatment, and it would serve a useful purpose incidentally in bringing to light cases attended by midwives concerning which they had omitted to advise that medical aid was necessary, and to inform the Council accordingly. Notification would render more complete the arrangements for securing continuous and efficient treatment of the child. The order would be advertised and a copy sent, as directed by the Public Health Act, to each qualified medical practitioner residing or practising in the county. The Council decided to make the compulsory notification order.

THE SCHOOL CLINIC AND THE LONDON COUNTY COUNCIL.

(FROM A SPECIAL CORRESPONDENT.)

THE debate at the London County Council on Nov. 1st concerning the medical inspection of school children and the letter of the Board of Education thereon turned very largely upon the question of treatment. The article on the medical inspection of London school children published in THE LANCET last week mentioned that the Council appeared ready to revise its present system of medical inspection and treatment, and this is certainly so. The necessity of the school clinic was touched upon by every speaker on the Progressive side, while from the Moderate side only Mr. Cohen and Mr. Cyril Jackson essayed to speak in favour of the hospital system of treatment. Mr. Cohen buttressed his defence of the Council's method by calling in evidence generalities about the charitable motives and good emergency work of the hospitals, but the relevancy of his remarks was somewhat vitiated by the fact that it was not the hospitals, but the Council's arrangements with them, which formed the subject of criticism.

The defence of Mr. Cyril Jackson, chairman of the Education Committee, was remarkable for its moderate tone. Mr. Jackson did not endeavour to deny that mistakes had occurred in the working of the hospital treatment scheme, but suggested that similar mistakes would have been inevitable even had a system of school clinics been established. And the further interesting suggestion was made, in the form one could not help thinking of a broad hint, that when the present hospital arrangements come to an end this year, the whole matter will come up for reconsideration.

The arrangements made by the London County Council embrace, among others, Charing Cross, Great Ormond-street, the London, and King's College hospitals, but exclude such important institutions as St. Thomas's, Guy's, St. Bartholomew's, Westminster, and University College. Quite apart, therefore, from the question of whether hospital treatment is suitable for school children as such, the County Council's arrangements were almost inevitably bound to be subject to serious faults in working. For instance, children living practically under the walls of a hospital with which no arrangements have been made by the Council have been sent miles away to another hospital for treatment under the scheme. Then some parents who have taken their children to a hospital directly after a medical inspector had indicated to them defects which required remedy, have been given an emergency treatment and told to apply to the head teacher of the school for a London County Council voucher entitling to further treatment. But the head teacher is not supplied with these vouchers, which are only issued after a delay of some weeks by the Education Office. The delay has the purpose of allowing the parent to provide treatment by his own endeavours, but in the cases cited it has the practical effect of considerably delaying treatment, frequently of rendering the emergency treatment futile, and of exasperating the parents and teachers alike.

The question of payment further complicates matters. The parent of every child treated at a hospital under the London County Council scheme must be assessed to pay for the cost of such treatment. So that after having been first delayed and subjected to waste of time and annoyance, the parent is secondly presented with a bill for treatment at a hospital at which his children formerly attended free, and at which they still attend free if under or above school age. And the parent is asked to pay notwithstanding any contribution he may have made to the hospital through his club, place of business, or personally, and despite any gift which he may make to the contribution boxes while actually attending the hospital.

Miss Adler, in a well-balanced speech, made this injustice clear and suggested further that the fee charged to parents was too high, and, in the case of a parent with several children needing treatment, more than a weekly wage-earner could be expected to pay without serious hardship. Another of the points made in the discussion was that some at least of the defects and diseases discovered by inspection are not such as the hospitals can conveniently tackle. The treatment of discharging ears, needing constant syringing twice or thrice a day by a nurse, is not a treatment for which the hospitals have either time or staff, while the treatment of discharging ears at home is admittedly liable to irregular intermissions, disregard of aseptic precautions, and lack of efficiency generally. Then there is the question of the operation for removal of tonsils and adenoids. This operation is rarely performed by the general practitioner on any but the wealthier among his patients, whereas the hospitals have more of this particular work than they can conveniently manage. In consequence there arise from time to time, cases where the children, after operation, have to be sent home by tramcar or omnibus in a condition, as Miss Adler said, unpleasant to themselves and to all who see them.

Both of these groups of defects and diseases appear to call for treatment in special school clinics. Much the same considerations apply to dental treatment, ringworm and other skin diseases, and also to those slighter degrees of dulness, nervousness, anæmia, and digestive troubles which are serious from the point of the teacher and school medical officer, but which, by comparison with the more acute and severe affections, do not, from the hospital point of view, warrant detailed and continuous treatment. A further consideration arises when the question of continuity of treatment in general is considered. There is, to begin with, no method of correlation of the hospital treatment and the school medical officer's inspection. The hospital does not accurately know what has been diagnosed by the school medical officer, nor in relation to what special school conditions. Nor does the school medical officer know in what way his diagnosis is being followed up by treatment.

Although the London County Council pays the hospitals, and the parent may have to pay the London County Council, there exists no way in which the parent can be compelled to continue regular attendance at the hospital with his child until the child is discharged cured. No organisation but that of a school clinic where the medical information gathered in school will be at the disposal of the physician or surgeon of the clinic, and where the attendance of the child can, if necessary, be compelled by use of the school authority, can get over these difficulties. This is particularly obvious when we examine the cases of the children of destitute or demoralised slum-dwellers who present a large proportion of defects. Among this class of case regularity of attendance at a hospital is a great rarity, even in severe cases. The parents will not, or often cannot, afford the time necessary to attend an ordinary out-patient department. For this reason children have been found in the schools suffering from tuberculous disease of the hip, with discharging sinuses, severe middle-ear disease, extensive (if under the clothing) skin disease, phthisis, and heart disease. Under existing conditions the children of this demoralised slum class do not and cannot get adequately treated, however great the efforts of individual hospitals and individual surgeons and physicians.

The debate at the London County Council on Tuesday made it abundantly clear that the treatment of the mass of defects and diseases discovered by medical inspection must be the work of a school clinic. Mr. Hobson, in addition to his carefully critical speech on the inspection question, Mr. Frank Smith, and every other speaker on the Progressive side, emphasised this point of view.

In connexion with any system of school clinics organised in London the hospitals must necessarily play a large part. There will be, in the first place, those cases discovered at school, which are too acute, or too severe, or require too specialised a treatment to be dealt with at the clinic. There will also be those cases where the parents of the child prefer to make their own arrangements with a hospital. Again, some of the special hospitals and special departments of hospitals could be arranged with so that what, in fact, would be clinics for school children within the walls of the hospital building could be organised. This applies to refraction, dental, nose, throat and ear, and chest cases. Where a special hospital or department exists in a district conveniently situate as regards surrounding schools, there seems every reason to think that suitable special arrangements could be made within the limits of the school clinic organisation, and as a part of that organisation.

The effect of the setting up of school clinics would be materially to disembarrass the out-patient departments of the hospitals, while more effectually treating the diseases found in school children. The effect on the private practitioner

would be in any case slight, as the organisation suggested amounts only to a redistribution for treatment purposes of the hospital population. It is even probable that in the redistribution the private practitioner would gain more than he would lose, while the school clinic would be a local organisation of service to him in cases requiring more continuous treatment than he could give, as in cases of discharging ears or minor surgical operations which it is impossible to undertake in poor homes and which now go to hospital.

THE MOTOR EXHIBITION AT OLYMPIA, LONDON.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

(*Concluded from p. 1364.*)

THE Ninth International Motor Exhibition is one of the finest representations of cars and accessories that have been held; but from the reporter's point of view it does not come up to the exhibition of 1908, in so far as that there is no striking new "copy-producing" feature such as the bomb which the Silent Knight engine then exploded on the public. Still, the show is certainly a worthy successor of the excellent ones that have preceded it. Buying a motor mount is, of course, not the same as the purchase of, say, a Gillette razor, for with the latter the blade, on account of its cheapness, can be thrown away when worn out. Such is not usually the case with a car, and it is therefore an advantage for intending purchasers to visit the exhibition, where they can see the many types of vehicle fitted for professional use, and consider the difficult question of which one is most suited for their individual needs. And yet, though I advise would-be buyers to go there to choose a car, I rather pity the layman who attempts to do so, because so many makers are represented by such good agents, and so many cars are so excellent, and are said to be so suitable for doctors, that the selection must indeed be a difficult matter. The one point above all others that should, I venture to submit, be kept in view by those who belong to what is known as "the motorists of moderate means class," is that the expenses of motoring are largely dependent on the load that is carried, and that there is much in favour of the light two-seater with hood and front wind-screen, at any rate for the doctor who is his own chauffeur. As to the number of cylinders, the tendency is in favour of four. Of course, there are many six-cylinders: probably more than there were last year. But for power, fair silence, and simplicity and efficiency the four-cylinder comes up to the requirements of most people, and a good many, I think, might with advantage, anyway in their early motoring days, be content with a single "lunger" like the De Dion, Rover, Swift, or Cadillac, though, of course, they do suffer in the matter of engine vibration on comparison with a four-cylinder.

Mr. Lloyd George has done good to motoring and motorists. His taxes on horse-power based on the bore and discarding the stroke are responsible for the number of smaller powered cars and the diminution in bore, coupled with increase in the length of the stroke. The popular size is undoubtedly 80 mm. bore by 120 mm. stroke, which comes for doctors within the £2 2*s*. tax. Such an engine, too, gives all the power likely to be required, and, of course, is economical in the matter of petrol.

A good many still cast their engines *en bloc*. Some makers, however, like the Darracq firm, have reverted to casting the cylinders in pairs. Except that this makes it easier to replace the engine covers, I do not think that it matters. If good oil is used for lubrication, and not too much, it will be of rare occurrence that pre-ignition will make a cleaning of the engine essential. Carbon deposits, too, are said to be removeable by the use of a chemical decarboniser, but opinions are divided as to its advisability. On another occasion I hope to be able to give the results of my own experience of this compound.

A large number of makers are using the Silent Knight slide-valve engine. The Daimler and Minerva companies started it, and now the Rover, Panhard, and Mercedes-Daimler are all building this type. Of course, when any engine is run hard, fast, and under load, it is not absolutely noiseless and without vibration, and probably the newer form may claim an advantage in these respects. Anyway, at present the poppet valves can be more easily repaired and adjusted than the slide valve, which seems an important point in favour of the former. Still, both are now so well made that breakdowns on either form are not likely to occur, and if they do—well, personally I should prefer the poppet engine. Some engines, like the Bentall, have overhead valves operated as on this type by an overhead cam-shaft, and other valves are operated by overhead rockers and by the usual crank case contained eccentric shaft. I do not quite see the advantage of the overhead valves, when they are lifted through rocking pieces that need long rods working in guides to reach the lifting cams in the crank case. However, as long as the moving parts are hardened it will be a long time before they wear enough to alter the lift of the valves, and if all the valves are on one side this method permits of larger valves being fitted, and the larger the valves the greater amount of charge, and thus an increase in power. To help to reduce noise the lift of the valves is reduced and the area increased, and that is why on some engines the inlets are on one side and the exhaust on the other, as with the White and Poppe and Austin engines. This, of course, means an extra cam-shaft. On many cars, too, to further deaden sound, the valve-lifting parts are covered in by easily detachable covers, as on the Napier and Austin.

The general tendency seems to be in favour of high tension magneto ignition, and this is now so satisfactory that many of the smaller cars rely solely on this method of exploding the mixture. Personally, however excellent it is, I prefer the knowledge that a second method is ready at hand, and the various forms of dual ignition shown by Messrs. Bosch, the Simms Co., and Messrs. Hall are all good, and medical men ordering cars could easily have one of them fitted in lieu of the single method or, what is as good, an already timed spare magneto can be carried. If this is decided on it is as well to see that the magneto is easily removable, and those held in position by a band are the best. On most cars it will be noticed that they are thus fixed.

Cooling is still on a good many cars assisted by a pump, but as this is now in all cases gear-driven trouble with this portion of the car's anatomy need not be anticipated. On many of the smaller cars thermo-syphon cooling is found sufficient. One good feature in the show is that on most cars the water-circulating pipes are of good size and on nearly all the radiator is helped by a circulating fan.

Lubrication is now in many cases maintained by some simple and out-of-sight form of pump which keeps a constant level of oil in the troughs under each big end. In some cases, as on the Daimler, the height of the oil in these troughs is varied with the speed of the engine, the throttle being connected, so that as it is opened they become deeper and, as closed, shallower.

Simplicity coupled with efficiency in carburetters seems the rule, and there are some excellent multiple jet arrangements. But still the single jet gives such good results that, generally speaking, the multiple jet form seems a needless complication. The spring controlled extra air valves also seem popular, which I believe accounts for the ability of the modern small engine to pull so well at low engine speeds.

Of clutches there are many, and the battle still rages between multiple disc and the leather cone. Personally, I prefer the latter, providing that some simple method to ensure slow engagement is fitted. Of course, accuracy of workmanship has more to do with the satisfactory working of a clutch than its form, and most cars by good makers have clutches that are excellent, whether they be multiple disc, leather cone, or expanding. The Metallurgique clutch is a good example of an internal expanding type, and on the Mors will be noticed an external form similar to the ordinary external band brake. The Austin fit a neat kind of leather cone, in which the leather is put on in segments, and on the Darracq too the cone is split radially at intervals round its edge, which also assists gradual engagement, and thus obviates fierceness.

Ball-bearings are universal for every part except the crank, and some makers, such as the Napier and Darracq, employ them also for the crank. The Hoffman, "F. and S.," and the Timken seem the favourite kind, and all are certainly of very superior make and likely to give satisfaction

Most gearboxes also are made with ball-bearings. On the F. and S. stand a crank is shown running by its own weight, and the way it spins when once set going is certainly a proof of the advantage of this method of reducing friction. Still, the multiplying of ball-bearings is simply a craze, for since a year I have driven a car with plain bearings without any trouble, and provided a plain bearing is well lubricated at the beginning worry in that quarter will not take place. However, the public are now keen on ball-bearings, and as makers are anxious to meet the wishes of possible clients the majority of cars are now so fitted—in fact, some cars perfectly bristle with ball-bearings.

The live-axle is now established, and the fight is not between chains and propeller shafts, but between bevel and worm final drive. The latter is becoming more common, and, provided it is well made, this form, which was first introduced by the Lanchester Company and Messrs. Dennis, has certainly the advantage of silence over its rival. It is, however, more expensive to turn out, and, of course, it increases the angularity of the propeller shaft. Practically every car has now one direct drive, and this year a large number of cars, and even small ones, are made with four forward speeds instead of the usual three, which is an undoubted improvement, especially on the lower-powered cars. At one time there was a tendency to make the direct drive the third speed, and to gear up the top one; but as all drivers naturally like, whenever possible, to be on the top, this method was not popular, as the top was not as silent as the third.

The majority of cars have still the foot-brake acting on the propeller shaft, and the hand-controlled one on drums on the back wheels. On some cars this is very wisely reversed, the foot-brake acting on the back wheels, as on the Stoewer car. On others both sets of brakes operate on the back wheels, as on the Straker Squire. On an increasing number of cars front wheel brakes are fitted—as, for instance, the Allen Liversidge, the working of which was described in THE LANCET last year, and is well shown on the stand of that firm in the gallery. Messrs. Crossley and the Argyll Company are amongst those who fit this kind of brake, which is undoubtedly superior as well as more safe on greasy, skiddy roads. They must, however, be employed with care to avoid interference with the steering.

The steering gear has of late years received more attention, and now undoubtedly is satisfactory—a very important matter, considering the danger that might result should this mechanism fail.

The springing of cars is certainly better than of yore, the general tendency being to make the springs flatter and to provide for their lubrication, with the result that there is now undoubtedly comfort without undue flexibility.

The tyres on most cars might still be more proportionate to the weight, and as an example of the advantage of heavier tyres it is to be noted that on the latest car built for the King tyres 965 mm. by 175 mm. are fitted. Of the tyres themselves, the Continental Tyre and Rubber Company, Limited (Stand 308), the Collier Tyre Company (Stand 296), the Dunlop Pneumatic Tyre Company (Stand 302), Messrs. George Spencer Moulton and Company (Stand 305), the North British Rubber Company (Stand 286), Messrs. Goodrich, Limited (Stand 300), the Michelin Tyre Company (Stand 307), the Palmer Tyre Company, Limited (Stand 181), and the Stepney Spare Motor Wheel Company (Stand 280), all show good examples of plain and non-skid productions. One improvement, however, I think we all would welcome is in the matter of price. As far as quality goes, there is marked alteration for the better. The combination of rubber with metal studs seems a good idea, but personally I believe the all-rubber non-skids, such as the Stepney or Kempshall, are the more efficacious and certainly last longer than the steel kind.

Among accessories the most striking novelties seem to be in the matter of electric lighting, which has great advantages for the motoring doctor. Messrs. Charles Jarrott and Letts, Messrs. Peto and Radford, Messrs. Fuller, and the C.A.V. Company all show interesting kinds of this form of illumination. In connexion with the dynamo lighting, it is possible for medical batteries, such as those used for X ray work, cautery, or electrolysis, to be recharged in the day-time while the car is in use, the dynamo current being taken direct to such batteries, thus charging them while the engine is running. Messrs. Longstreth's and Brown Brothers also show a good assortment of motor head, side, and tail lamps.

In the coachbuilding exhibits there is one satisfaction—the English builder competes well with foreign competitors. All types are shown, from the modest two-seater to the sumptuous landaulette, and the various creations of such firms as Barker, the Gordon Carriage Works, Holland, Hora, Lawton, Maythorn, Mulliner, Morgan, Salmons, W. and F. Thorn, and Thrupp and Maberly show well the present-day improvements in contour and comfort. Those who rode 12 years ago in the old Benz cars, with their dog-cart bodies and solid tyres, will appreciate the change. As examples, one has but to look at such little two-seaters as the Swift, Darracq, or De Dion, or the Medicann closed-in two-seater, as well as the torpedo, limousine, and landaulettes which abound in the Long Acre part of the show. High fronts, side doors, and adjustable wind-screens seem the rule, and all add greatly to the comfort of driving in the variations of weather that we have to put up with in this country. The only grumble that I can make is that when the Cape-cart hood is up some wind-screens make getting in and out of the car rather a difficult performance.

In continuation of my short notes last week about particular exhibits, there are a few more which deserve mention. The Tribet Car is shown by the Motor Mercantile Co., Limited, of Duke-street, W., on Stand 4, and is well fitted for a two-seated cabriolet body. The four cylinders are cast in pairs, and have a bore of 70 mm. and a stroke of 100 mm. The valves are on each side, and are interchangeable. The carburetter is a Claudel-Hobson, and ignition is by Bosch magneto. The radiator is of the grilled pattern, and the circulation is assisted by means of an efficient pump. The gearbox provides for three forward speeds and a reverse operated by a single lever, and the transmission is by cardan shaft and the usual bevel gears. The brakes are of the internal expanding type, and the car is in every way of sound up-to-date construction.

Messrs. Armstrong, Whitworth, and Co., of Blenheim-street, New Bond-street, W., on Stand 60, show two useful sized models, of 15·9 h.p. and 17·9 h.p. The latter has an engine 85 mm. by 120 mm., a multiple disc clutch, dual ignition, tyres 815 mm. by 105 mm., and detachable wire wheels. The pressure-feed to the petrol tank is operated by a mechanical pump, and all the valve mechanism is enclosed. These cars are sold with a comprehensive insurance policy that covers not only third-party claims and accidents, but mechanical breakdowns also.

Not only is there a fine array of cars on Stands 129 and 71, where Messrs. Crossley Bros., of Manchester, are exhibiting, but their cars are especially interesting in view of a very ingenious method of front-wheel braking which should certainly be inspected.

The Gladiator Company, of Great Portland-street, W., now only build two models—a 12–14 h.p. and a 35–40 h.p. The smaller has genuine good workmanship and is fitted for either a two-seater or a small four-seated body.

Messrs. Humber of Coventry have always been popular with the profession, and their 1911 four models are bound to maintain the reputation of their predecessors. Among many features are chain-driven cam-shafts and the use of the propeller shaft casing as a torque rod. Detachable wire wheels are fitted, and though their prices are somewhat advanced, I do not think that this will in any way affect their popularity.

The cars that are "made like a gun," by the Enfield Company, of Sparkbrook, Birmingham, are just to the right of the Hammersmith-road entrance on Stand 90. The 12 h.p. has a four-cylinder engine, 75 mm. by 100 mm., with enclosed valves and tappets on the near side, cooling being by thermo syphon, and ignition by gear-driven magneto. The clutch is a leather-faced cone. There are four forward speeds, controlled by the usual gate. On the 20 h.p. either the third or fourth speed can be supplied as direct.

On Stand 56 Messrs. Rolls-Royce, Limited, of Conduit-street, W., merely show the chassis of their only production, a six-cylinder, the price of which is, roughly, £1000, and yet, in spite of this figure, I understand that a very large number of orders have been booked by this firm. The engine should certainly be seen, as it represents all that is latest and best in the matter of a six-cylinder.

The Sizaire-Naudin Car, made by Messrs. Jarrott and Letts, of Great Marlborough-street, W., is on Stand 71, and is chiefly famous because the change-speed mechanism is incorporated in the back axle-casing, and by the engaging of different small bevels with the crown wheel all the speeds are

direct. This car, which was described in THE LANCET of March 27th, 1909, can now be had with either a single- or a four-cylinder engine.

Messrs. Clement-Talbot, of North Kensington, are on Stand 51, where they show specimens of their four models, as well as an enormous number of medals—a proof of the many successes they have obtained in competitions with their cars. This firm have been the earliest advocates of the now popular four-speed gearboxes, and the automobiles shown are in every way worthy of their name.

REPORT OF THE COMMISSIONERS OF PRISONS AND THE DIRECTORS OF CONVICT PRISONS FOR THE YEAR ENDED MARCH 31ST, 1910.

THE Prison Blue-book for the year 1909–10, in accordance with the practice adopted some years ago, has been issued in two parts, the first containing the reports of the Commissioners and of the several inspectors, together with the usual statistical tables referring to the general prison population, while the second part gives detailed information regarding the different local and convict prisons, Borstal institutions, and State inebriate reformatories.

The total number of prisoners received into local prisons during the year was 216,148—173,800 males and 42,348 females, these figures showing a slight decrease on the numbers for 1908–09. There were 82 deaths from natural causes during the year, giving a death-rate of 0·38 per 1000 prisoners received, the average rate for the last five years being 0·42. Nine deaths were due to pulmonary tuberculosis, and it is remarked that the disease existed prior to reception in all the cases save one. Five prisoners committed suicide. Sixteen cases of infectious disease were reported during the year, the infection having in most instances been contracted prior to the prisoner's admission.

The number of prisoners certified insane in local prisons last year was 118—viz., 106 males and 12 females. The medical inspector remarks that, though there has been a slight tendency to a decrease in the number of these cases, the fact is not an indication of any increase of discrimination on the part of the committing magistrates, for the ratio of prisoners found to be insane on reception to the total number certified has remained fairly stationary. It would appear, therefore, that there is still room for improvement in regard to the investigation of the mental condition of accused persons, and that if more care were exercised by magistrates it would be possible to avoid, or at all events to abate, the scandal of sending lunatics to prison. As evidence of what might be done by a more liberal use even of the existing machinery, the medical inspector points to the excellent results of the growing practice in the larger centres of remanding prisoners of doubtful mental condition for the expert examination of the prison medical officer. This is done very freely in the metropolis, where the medical officers of the two prisons, Brixton and Holloway, which receive prisoners on remand, were called on last year, for instance, to report to courts of summary jurisdiction on the mental state of nearly 900 accused persons, a considerable proportion of whom were found to be certifiably insane. Moreover, of course, all prisoners committed to these prisons for trial at assizes and quarter sessions are specially examined with regard to their mental condition, and evidence on the point is furnished to the courts. The good effect of this sifting process is seen in the fact that in the metropolitan prisons the proportion of cases in which insanity is not recognised till after the sentence is much below the average for the country at large. Thus during the last five years the three London prisons for convicted males—Pentonville, Wandsworth, and Wormwood Scrubbs—which receive over 28 per cent. of male convicted prisoners in England and Wales, have only contributed 16·1 per cent. to the total number of prisoners certified insane after conviction. And similarly Holloway, though receiving more than 30 per cent. of the women sent to prison in this country, has in the same period furnished less than 13 per cent. of the cases of insanity in convicted females. That this is mainly due to the cause indicated above, and not to any lack of insane offenders in London, is shown to be very probable by the fact that Holloway accounts for upwards of 60 per cent. of the cases of women on remand who were reported as insane to courts of summary jurisdiction.

During the year 322 convicted prisoners were specially dealt with under the modified rules for prisoners so feeble in mind as to be unfit for ordinary penal discipline. In this connexion it is satisfactory to note that the Commissioners announce that in compliance with the desire of the Secretary of State they have submitted definite proposals for dealing with the problem of the feeble-minded offender. It is suggested that legislative sanction should be obtained to empower the Secretary of State "to transfer prisoners to special institutions, under due safeguards, on medical certificate (analogous to that given in cases of insanity) that a person under sentence is so clearly defective in mind as to be unable to earn his own living or to take ordinary care of himself, and to be likely to revert to crime on discharge unless special means are taken for his supervision." If this suggestion is carried out, and if the class of mentally defective delinquents can be dealt with at once and independently of the general problem of the feeble-minded, it is considered that an institution for about 500 would be required at the start. It may be hoped that this announcement indicates that the Government are prepared at length to take action on this matter, the urgency of which has been so constantly pressed on their attention by the Commissioners for several years past. Some idea of the difficulty of dealing with the heterogeneous material which under the existing system has to be managed in prisons can be gained from the very remarkable report of the medical officer of Pentonville Prison, Mr. J. H. Parker Wilson, published in the second part of the Blue-book, in which he gives an account of the feeble-minded, the epileptics, the vagrants, and the inebriates admitted to that institution in the course of a single year.

The daily average population in the convict prisons last year was 3069 males and 120 females. The deaths during the year numbered 22, all but one being due to natural causes, giving a death-rate from such causes of 6·5 per 1000 of the daily average population. Thirty-six convicts were certified insane.

The medical officers of the Borstal institutions are emphatic in calling attention to the excellent results in improved physique and nervous tone which have been obtained by the physical exercises and the general discipline enforced on adolescent prisoners under the Borstal system. It is gratifying to learn that the Commissioners see some prospect of being able to modify the limitation which has hitherto excluded lads in bad health or of poor physique from the operation of this system. The opening of a new Borstal institution at Feltham may, it is hoped, provide enough additional accommodation to allow of the formation of a special class for those adolescents whose physique renders them unfit for the full measure of drill and gymnastic exercises. The efforts being made to develop the Borstal methods and to further other reforms tending to substitute the educative and preventive for the purely deterrent influences in the penal system afford gratifying evidence of the spirit which animates the prison administration under the *régime* of Sir Evelyn Ruggles-Brise. Amongst the appendices to the report special reference may be made to a very interesting inquiry by the secretary of the Prison Commission, Mr. Basil H. Thomson, regarding the question of recidivism. Taking advantage of the improved means of identification provided by the finger-print system, Mr. Thomson has investigated the after-history of 4563 convicts discharged in the five years 1900 to 1904 and has found that 30 per cent. have not relapsed into crime, and that of the apparently confirmed recidivists as many as 17 per cent. have kept out of trouble. Considering the quality of the material this is a very encouraging result, and goes to prove that the more humane methods now in vogue are exercising some real reformatory influence.

ROYAL SOCIETY OF MEDICINE (BALNEOLOGICAL AND CLIMATOLOGICAL SECTION).—A general meeting of this section was held at 15, Cavendish-square, W., on Oct. 28th, Dr. T. F. Gardner (Bournemouth), the President, being in the chair. The President gave an address entitled "Air and Water: Is there anything New under the Sun?" The same evening the annual dinner took place at the Imperial Restaurant, at which Sir Thomas Barlow and Dr. Bertrand Dawson were guests.

COLONY OF HONG-KONG: PUBLIC HEALTH REPORT FOR 1909.

IN the recently published volume of medical and sanitary reports for Hong-Kong there is a joint report on the public health of the colony for 1909 by the principal civil medical officer and the medical officer of health.

Personnel: Reduction of Inspectorate.

In noticing a previous issue of these reports we gave particulars of the area administered by the Sanitary Board of the colony. The mixed character of the population was also indicated, the European being distinguished from the native and the civil from the military and naval inhabitants of the district.[1] The *personnel* of the Hong-Kong sanitary department has changed considerably since 1908. Dr. J. M. Atkinson still contributes the civil portion to the report, but the sanitary and statistical portion is now authenticated by Dr. Francis Clark, in place of Dr. W. W. Pearse, who has been transferred to Kowloon as assistant medical officer of health. The sanitary inspectors of Kowloon work under Dr. Pearse's personal supervision, but the sanitary inspection of the remainder of the colony seems to be delegated to the local police. Since the year 1908 a general improvement in the public health of the colony has been observed, and this fact has unfortunately been held to justify a large reduction of the inspectorate, for the five special plague officers hitherto employed have been dismissed, their important preventive duties being apparently left to the ordinary district inspectors. From what can be gathered from recent reports concerning the imperfect sanitary defences of Hong-Kong against the ravages of plague, this serious reduction of the expert staff seems to be a retrograde step. We shall therefore be interested to learn how far it has been sanctioned by the medical authorities locally responsible for the maintenance of the public health.

Vital Statistics.

According to the best estimates available, the total population of the colony in 1909 numbered about 344,000, of whom rather more than 323,000 were either Chinese or Malays, and of these 46,000 were included in the "boat population." The civil population consists mainly of male adults. At the 1901 census 72·6 per cent. of the inhabitants were males. At the last census (1906) the proportion fell to 70·1 per cent., so that there has been during that interval an increase in the proportion of females, which means an improvement in family life among the Chinese. More than half of the civil inhabitants are between the ages of 20 and 45 years.

For reasons given in the previous report, the medical officers repeat their warning that the registered number of Chinese births affords no trustworthy measure of the true birth-rate. Owing to the custom of registering the births of only those children who survive the age of one month, the reporters indicate the proportion of 7·0 per 1000 of the Chinese population as the maximum rate of natality that can justly be recorded for the year 1909. Very remarkable is the preponderance of male over female births registered among the Chinese. In the year under notice not fewer than 266 males were born to every 100 females. Among the non-Chinese community the male births were in the ratio of 117 to 100 female births, a proportion which approaches more nearly than the foregoing to that of this country. The mortality in Hong-Kong varies considerably from time to time. Last year the rate was equal to 21·1 per 1000 living, against a rate of 27·6 per 1000 in the year immediately preceding. Of the total deaths at all ages about one-third were those of infants under one year old. Among the Chinese population the *known deaths* of infants numbered 2260, whilst only 1202 births were registered; if to these be added the unregistered births of children under one year of age that died in convents or that were found dead in the streets the total deaths will amount to 2588, a number corresponding to an infantile mortality which must be considered enormous.

In this report the deaths from pulmonary tuberculosis are included with those from other diseases of the respiratory system, and these together account for more than one-third of the mortality from all causes. Among the Chinese the deaths from respiratory diseases in the year 1909 corresponded to a rate of 7·8 per 1000 living, and those from pulmonary tuberculosis to a rate of 2·3 per 1000. In that year these latter deaths were in the proportion of 10·7 per cent. of the total deaths, as compared with 9·8 per cent. in 1906—a fact which is regarded by the reporters as indicating that the deaths from this disease are proportionally on the increase, although the total mortality is less.

Malaria, Plague, &c.

The loss of life from malarial fever has been decreasing slightly since the year 1907. Last year 422 deaths were referred to it, all but five of which were among the Chinese. In this colony definite preventive measures against malaria were first undertaken in 1899, since which year considerable attention has been directed to the work. The inspectors have diligently sought for and removed the breeding-places of mosquitoes, dense tangles of brushwood have been cut down, the "trained nullahs" have been regularly swept to prevent the growth of waterweed and of algæ, and stagnant water has in many places been periodically treated with kerosene; and further, the ordinary methods of house fumigation with sulphur have been carried out in suitable cases. Hygiene is taught systematically in all the schools of the colony, special attention being paid to the mode of malaria infection by the mosquito, as well as to the manner in which the mosquito breeds. The total number of cases of plague reported last year was 135, as compared with 1073 in the preceding year, and 893 and 240 respectively in the years 1906 and 1907. Thirty-one of the cases occurred in Kowloon city, a native city of old rat-ridden dwellings, which only came under British jurisdiction in 1899 and has not yet been rebuilt. Of the 135 reported cases 108 died, the mortality among the non-Chinese being 57 per cent. and among the Chinese 81 per cent. It is well known that rats are chiefly instrumental in distributing the infection of plague, and in Kong-Hong a special rat-poisoning campaign is instituted annually just before the onset of the usual epidemic season—i.e., during January, February, and March. In the course of last year 60,000 rats were killed in the city of Victoria and 16,000 in Kowloon; of this number not fewer than 407 were found, on bacteriological examination, to be infected with plague. Among other infectious diseases enteric fever is reported to have been somewhat more prevalent than usual last year, whilst with this exception the colony appears to have been comparatively free from ordinary diseases of the epidemic class.

[1] THE LANCET, March 19th, 1910, p. 817.

SANITATION IN INDIA.

IN continuance of our custom we present our readers with a brief review of public health matters in the Indian Empire, described from the official annual reports, with which we have been favoured by the courtesy of the authorities concerned. Although we are nearing the close of 1910 we have not yet received the whole of the 1909 series of reports; indeed, from Madras the only one that has come to hand is the report on lunatic asylums. The reports from the senior Presidency seem to be generally somewhat tardy in arrival. Neither have we the vital statistics from the other Presidency administrations of Bengal or Bombay. The collection and preparation of statistics from these enormous populations and from such wide areas is, however, we are well aware, a very long business; the mass of figures is appalling. Great care has been exercised in the printing of these reports, which shows marked advance on the typographical work of some years back. We shall deal first with the general sanitary administration, then with the civil hospitals and dispensaries, then with the jails and asylums.

I.—SANITARY ADMINISTRATION.

United Provinces of Agra and Oudh.

The Report of the Sanitary Commissioner for the United Provinces of Agra and Oudh for 1909 is the forty-second annual issue. The vital statistics are, as usual, calculated on the population according to the census of 1901. No other method is feasible, but obviously, in the eighth year after enumeration, the figures for 1901 do not afford an accurate basis for the calculation of ratios. Both birth-rate (33·32

per 1000) and death-rate (37·34) were below the quinquennial means (41·35 and 42·79 respectively); the former is accounted for by the extreme unhealthiness of these provinces, due to malaria, in the preceding year (1908), the latter to the weeding out of the weakly and aged in 1908 from the same cause. It is noted that the (monthly) birth-rate rose steadily from 1·59 in July to 4·05 in December; and that this rise was most marked in the districts where malaria had been most severe, and the previous diminution most noticeable; so rapid a recovery is a striking instance of the tendency of nature towards equilibrium—*tamen usque recurret*. The death-rate (37·3) was much lower than the very high figure (52·7) in 1908; but was nevertheless considerably higher than in any other province in India. The infantile mortality (241·6 per 1000), though less than the high ratio (345) in 1908, is still excessive; from an inquiry conducted by a lady doctor specially appointed for the purpose, it appears that 30 per cent. of these infantile deaths result from tetanus. In regard to all causes of death except plague, these provinces suffered less than in 1908. Plague, however, increased in severity, and caused 38,394 deaths, the mortality increasing towards the end of the year. The malarial mortality was high in certain districts that had been severely affected in 1908, and decreased in the latter part of the year. Arrangements have been made to secure early notification of malarial prevalence, and an effective free distribution of quinine should an epidemic occur. At Chakrata 62 cases of a fever intractable to quinine were reported, which on bacterial investigation at the Kasauli laboratory were found to be relapsing fever; there were ten deaths, but measures were promptly taken and the spread of the disease checked. At Naini Tal there was a recrudescence of enteric fever, 45 cases amongst natives and 23 amongst Europeans being diagnosed; nine of the European cases were residents at St. Joseph's School; on investigation by Captain E. D. W. Greig, I.M.S., a carrier was detected employed in the cookhouse of this institution; the man was discharged and no cases occurred subsequently. No allusion is made to the military depôt for typhoid convalescents at this station; its presence has not presumably had anything to do with the outbreak just mentioned. At Benares biological methods of sewage treatment are carried out; ordinary contact beds and two secondary beds are in use, and are stated to be working well. Two great fairs took place during the year, one at Allahabad in February, the other at Hardwar in April; only one case of cholera occurred on the former occasion; at Hardwar (where some 300,000 people were gathered together) there were 156 deaths from this cause. In former days the deaths would have run into thousands and the epidemic spread over half a province; only those who know the conditions can appreciate the unceasing vigilance and administrative skill that must have been displayed in dealing with these emergencies. Major J. C. Robertson, I.M.S., officiating Sanitary Commissioner, has paid particular attention to the causes underlying the prevalence of malaria in the Naini Tal Tarai, and has completed malarial surveys of the two excessively feverish towns, Saharanpur and Nagina. This officer furnishes the present report, but the Sanitary Commissioner during the year was Colonel C. C. Manifold, I.M.S.

A special report is forwarded by Colonel Manifold, now Inspector-General of Civil Hospitals, on the prevalence of plague in the United Provinces during the twelve months, July, 1909, to June, 1910. The services of the medical officers who had been appointed in 1907 to superintend plague inoculation, conservancy measures, and the destruction of rats were dispensed with (except at Cawnpore) in April, 1909. In July Government directed that all expenditure on special measures against plague should be discontinued until it broke out again in epidemic form, and that before any measures involving expenditure were undertaken the sanction of Government should be obtained. These orders were strictly observed. During the year (July, 1908, to June, 1909) there had been 15,580 seizures and 13,814 deaths. From July, 1909, to June, 1910, there were 151,298 seizures and 141,357 deaths. Comment is unnecessary.

The main feature of this epidemic was the much higher mortality in 1909 than in 1908 during the months July to November: the deaths numbered only 381 in 1908; they were 10,550 in 1909. In December, January, and February the mortality continued to increase, until in March, 1910, the total plague deaths reached 39,513; thereafter the disease rapidly abated, until in June there were only 280 deaths. More than half the deaths (74,989) occurred in the four most easterly districts, Ballia, Ghazipur, Azamgarh, and Gorakhpur. Inoculation proved to be a very unpopular measure; the belief that it causes impotence is widespread, and the fear of this calamity is greater than that of dying from plague. Where inoculation succeeded it was owing to the tact of the medical staff and in some cases to the good example of some man of influence; if such a person was himself inoculated, with the whole of his family and his zenana, the entire village would very likely follow his example.

Central Provinces and Berar.

In the Central Provinces and Berar the duties of Sanitary Commissioner were combined with those of Inspector-General of Civil Hospitals under Colonel P. A. Weir, I.M.S., until Feb. 1st, 1910. On that date the departments were separated, and Captain T. Stokes, I.M.S., was appointed Sanitary Commissioner. The report for the previous year is his work. The birth-rate, 51·63 per 1000, was higher than in any other province; but, as already remarked, these rates are subject to much correction, as the census figures have become obsolete. The general death-rate for 1909 was 33·09 per 1000, the third highest in India, but lower than in any of the preceding six years in these provinces. Neither cholera nor small-pox prevailed to any considerable extent, though the former disease was introduced by pilgrims returning from Benares and Nasik into several districts. Malarial fevers accounted for 15·08 per 1000, nearly half of the total mortality; the number of deaths amounted to 180,544, but this was a considerable improvement on the previous year. No special antimalarial measures were carried out. Plague prevailed in Nagpur town and district, and to a slighter extent in several other places. The Sanitary Commissioner considers that rat destruction is practically a hopeless task and mere waste of money.

Punjab.—North-West Frontier Province.

The report on sanitary administration in the Punjab for 1909 is of a much more satisfactory character than that for the previous year. The climatic conditions were generally favourable to the public health, there was comparatively little malaria, food was cheap, and the general prosperity increased. The death-rate, 30·89 per 1000 (as compared with 50·73 for 1908), was the lowest since 1900. Cholera and small-pox were not extensively prevalent. There was a slight increase in plague; the value of inoculation is not recognised by the population at large, and in regard to rat destruction they are apathetic. It is stated, however, that the country people are showing a gradual tendency to evacuate infected villages of their own accord. The severe malarial outbreak of the previous year did not come to an end until the spring of 1909, but the rest of this year was singularly free from the disease; quinine distribution is carried out on a large scale. It is noted with satisfaction that the municipal committee of Lahore is active in taking measures to improve the sanitary condition of the city, and that the general public are more alive to the importance of sanitation than they used to be.

The North-West Frontier Province had a satisfactory sanitary record in 1909: the death-rate, 26·6 per 1000, was the lowest returned since the formation of the province, and lower than any other in India for the year, except Madras. It is noted that vaccination is now fairly well accepted by the people; the small-pox mortality has fallen to 0·32 per 1000.

Burma.

In Burma there was an increase in mortality in 1909 over the two previous years, the death-rate from all causes being 30·18 per 1000; this increase was confined to Upper Burma, where the rate was 34·81, Lower Burma having a rate of only 27·70; the cause for the increase was prevalence of cholera, fevers, and plague in the Upper Province. Major C. E. Williams, I.M.S., Sanitary Commissioner, gives considerable attention to the very high mortality of infants under one year, 222 per 1000; but the conclusion arrived at is that the registrations of birth are incorrect. Though Lower Burma suffered less from cholera than in the previous year, in Upper Burma there was a heavy mortality in nearly all areas; the fact is, the water-supplies are everywhere open to pollution. Mandalay experienced a sharp outbreak with 795 deaths.

The river water is preferred to the well water for drinking by a large proportion of the townspeople, and the water-carriers fill their barrels at that point where native shipping congregates. "It appeared on inquiry," says the Sanitary Commissioner, "that legal powers do not exist to prevent the water-carriers from taking water for sale from any point of the river bank which they find most convenient." It seems to us that whether they had legal powers or not, the municipal or police authorities might have prevented this obviously dangerous practice and saved a large proportion of the 795 lives lost; the legality could have been argued out afterwards. Mandalay also suffered severely from plague, there having been 2366 deaths. In regard to the province generally it is stated that no marked advance was effected in protecting the town and country populations from plague, local sanitary action and rat destruction only being adopted after the presence of plague in a locality was recognised. The only measure of real value after the appearance of the disease is considered to be evacuation, which was carried out with good effect in several districts. In Rangoon more than a lakh of rupees was paid to the public for rat destruction during the year. It is pointed out that for less than half this sum a properly organised municipal establishment for the purpose could have been maintained, fraud having been practised by the public, by bringing in rats from outside in order to claim the reward. Experiments conducted by Captain R. D. Saigol, I.M.S., at Maymyo resulted in the preparation of a virus for rat destruction which retained its efficacy for apparently an indefinite period, and which was intended to be extensively used during the ensuing quiescent season.

Eastern Bengal and Assam.

From the report on the province of Eastern Bengal and Assam, by Major E. Wilkinson, I.M.S., Officiating Sanitary Commissioner, we learn that the most noticeable feature in the vital statistics for 1909 was an increase in the mortality from small-pox, which rose to 0·79 per 1000, being most prevalent in the rural areas, where it was more than three times the decennial average. In the Rangpur district, in some villages whole families were swept away, these places being those where the inhabitants persistently declined vaccination. The total death-rate was 33·89, fevers contributing 24·56 per 1000; this coincided generally with an excessive rainfall. Following on some recommendations by Dr. C. A. Bentley, changes both in the form of quinine issued and its method of distribution are now being adopted. Instead of the doses of quinine that have hitherto been sold or distributed gratis it is proposed to issue "treatments," each containing 20 four-grain tablets of the hydrochloride, packed in a glass phial with directions for use, and instructions as to personal prophylaxis. This is the method that has been carried out so successfully by the Italian Government. Anti-malarial operations were undertaken vigorously at Dinajpur and elsewhere; the results were not so successful as had been hoped for, but were encouraging; at Dinajpur fevers accounted for 59·47 per cent. of the total mortality, against 81·29 for the preceding five year-period, but Captain D. P. Goil, I.M.S., confesses to have been disappointed to find breeding places which had been cleaned and thoroughly kerosined still swarming with mosquito larvæ.

A valuable supplement is issued with this report, containing the results of special investigations into outbreaks of plague, cholera, beri-beri, and epidemic dropsy; also reports on water-supplies and drainage schemes. The papers are after the manner of those in the appendix to the report of the medical officer to the Local Government Board. The accounts of two outbreaks of pneumonic plague, in which Captain C. A. Gourlay, I.M.S., carefully traces the course of the infection, are most interesting; in Eastern Bengal no trace of rat infection was found, neither has bubonic plague ever spread epidemically, but the pneumonic outbreaks have been most virulent. Captain Gourlay also describes an outbreak of cholera, and states that he has been informed on good authority that fakirs have a system of blackmail: they demand money to prevent a village getting cholera, and if not satisfied deliberately infect the wells. An outbreak of epidemic dropsy at the Dacca lunatic asylum in 1908 is described both by Captain M. F. Reaney, I.M.S., and Lieutenant-Colonel R. N. Campbell, I.M.S. There were 158 cases, occurring within 15 days, in a population of 270. Colonel Campbell attributed it to some rust or fungus growth on the rice consumed, this poison having a special effect on the sympathetic system; Captain Reaney considered it might be of the nature of a food poisoning, though no particular article could be blamed. Captain T. H. Delaney, I.M.S., investigated the prevalence of beri-beri in the jails of the province, and came to the conclusion that none of the epidemic outbreaks of dropsy during recent years have been true beri-beri, there having been no true paralysis or anæsthesia; but that the disease in question was infectious dropsy spread by means of bed bugs. Two valuable papers are contributed by Dr. Bentley and Major Wilkinson on Practical Points of Quinine Prophylaxis. The records of investigations contained in this Blue-book (price 11 annas, or 1*s.*) should be in the hands of all medical officers engaged in sanitary work throughout India. It is to be hoped that the volume is as widely known and accessible as it deserves to be.

(To be continued.)

Public Health.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances and Administration of Bakewell Rural District,[1] by Dr. REGINALD FARRAR.—This report relates to a large area in the north of Derbyshire, which comprises many villages and hamlets well known to visitors to "The Peak." Particular attention is directed to the condition of local water-supplies, some of which are by no means satisfactory. Thus at Elton the supply consists only of a public dip-well, inconvenient of access, failing in dry weather, and fed by a spring which is liable to pollution. Pure water-supplies are needed at Monyash to replace the existing roadside reservoir and public wells; at Flagg, where water is drawn by bucket and windlass from the bottom of an old lead shaft, and is hard and subject to contamination; and at Earl Sterndale, where the villages depend chiefly upon rain-water collected from the roofs and at other places. The main village of Eyam derives its water from seven public troughs, fed by streams which in most cases are liable to surface pollution, while the water issuing from the troughs is often reduced to a mere trickle, so that the process of obtaining half a gallon of water occupies several minutes. There is, however, an abundance of excellent water in springs on the hillside above Eyam which should be made available for a public supply and piped to the houses. In several of the parishes in the district public supplies of a satisfactory kind have been provided. Where water is derived from moorland sources and is liable to act on lead, special care has to be taken to apply an appropriate treatment, such as the addition of lime, before it enters the service pipes. Neglect of this precaution in the case of the Stoke Flat water has on more than one occasion resulted in the occurrence of lead poisoning among the consumers. Bakewell rural district is included in the Haddon joint hospital district, established by the Derbyshire county council in 1897 under the Isolation Hospitals Act, 1893. The joint hospital board, which includes representatives of nine sanitary districts, has during the past 13 years considered and rejected ten sites for the construction of its hospital. The temporary arrangements made during this period of deliberation have been quite inadequate. Six beds rented at the Whitworth Hospital at Darley Dale appear to be the only provision available for the reception of infectious cases in this part of Derbyshire.

On the Sanitary Circumstances and Administration of the Borough of Bridgnorth,[2] by Dr. F. ST. GEORGE MIVART.—Stress is laid in this report on the dangers of a filtered water-supply derived from the Severn. The intake is only about 50 yards below the point where the Cantern brook, recipient of the effluent from the borough sewage works and the washings of the town refuse tip, flows out, while the river above the intake receives polluting matter at other points. The filtration formerly took place in sand filters; recently it has been effected by the experimental use of pressure filters, estimated to be capable of filtering 250,000 gallons in ten hours. This Severn supply is intended to be used for purposes other than drinking, and a duplicate supply of spring

[1] Reports to the Local Government Board on Public Health and Medical Subjects. New Series, No. 37. London: Wyman and Sons; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 4*d.*

[2] Ibid, No. 25. Price 3*d.*

water of good quality is also laid on to the town. The Severn water, however, has undoubtedly hitherto been used for drinking, and in Dr. Mivart's view is likely to be so used even more in the future. The population of the borough of Bridgnorth has not shown any increase in recent years, a circumstance to which the unsatisfactory character of some of the older house property and the general shortage of houses probably contribute. Dr. Mivart found that the need for cottages for the labouring population, particularly for such as have families, was very great. The shortage was not confined to dwellings for the poorer class. Rents are high—in some cases remarkably so, considering the accommodation afforded. An unsuccessful attempt was made by the town council some years ago to proceed with a scheme for erecting working class dwellings; it would seem in the interest of the town to make effective progress in this matter.

On the Sanitary Circumstances and Administration of the Clutton Rural District,[3] by Dr. R. J. REECE.—As in many other rural areas on which reports have been made by inspectors of the Local Government Board, the district of Clutton suffers from insufficiency of housing accommodation. Although a considerable amount of building is now being carried on in the larger villages, nevertheless, in these as well as in the more rural parts, people were found occupying houses so insanitary and so dilapidated as to constitute "uninhabitable" houses. Most of them live in these conditions because they cannot find more suitable houses to move to; and they are permitted so to live lest by their ejectment overcrowding in other houses should be brought about. The demand for more dwellings is increased by coal-mining operations in the district, which will probably be extended and so increase the demand. By the terms of the Housing and Town Planning Act the district council can provide house accommodation for miners working at the coal-pits, and Dr. Reece indicates that this course should be followed if the necessary housing is not forthcoming through private enterprise. The greater part of the district is now served by public water-supplies, but the water available is in certain instances liable to possible pollution. In an important supply termed the "eight parishes," furnished by pumping from a well at Gurney Slade, the danger lies in polluting matters being drawn to the well from villages which appear to lie on the gathering area, and from the existence in this part of the country of numerous "swallow-holes" and fissures in the strata which may be the receptacles of sewage from houses and groups of dwellings.

On the Sanitary Circumstances and Administration of the Holywell Registration District,[4] by Dr. E. P. MANBY.—As a result of an extensive and detailed inquiry in this registration district, which comprises the larger part of the county of Flint, Dr. Manby makes a strong recommendation in favour of the appointment of a whole-time medical officer of health. "At present, in the Holywell Registration District six district councils profess to combat insanitation and infectious disease with the aid of four medical officers of health and seven inspectors of nuisances. Each medical officer is entirely independent of the others, and each inspector is practically independent, not only of the other inspectors and medical officers, but of the medical officer of his own district. In result, uniformity and continuity of action in health matters are wanting." Examples are given of the numerous shortcomings of the several districts referred to, and there can be little doubt that the present arrangements have been wasteful and inefficient. A scheme for combination is given, and the arguments habitually used against such appointments are set out and dealt with in a way which should facilitate agreement between the districts concerned, if they are disposed to come together in the absence of action by the Local Government Board which would oblige them to make the arrangements recommended.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 7851 births and 4250 deaths were registered during the week ending Nov. 5th. The annual rate of mortality in these towns, which had been equal to 13·0 per 1000 in each of the two preceding weeks, rose to 13·1 in the week under notice. During the first five weeks of the current quarter the death-rate in these towns averaged 13·0 per 1000. In London the death-rate during the same period, calculated on the probably over-estimated population, did not exceed 12·7 per 1000. The lowest reported annual death-rates last week in these 77 towns were 5·7 in West Hartlepool, 6·3 in Willesden, 6·4 in Warrington, and 6·7 in East Ham; the rates in the other towns ranged upwards to 18·8 in Wigan, 19·4 in Tynemouth, 19·5 in Swansea, and 20·5 in West Bromwich. In London the reported death-rate last week did not exceed 13·1 per 1000. The 4250 deaths from all causes registered in the 77 towns last week showed a further slight increase of 28 upon the numbers in the two preceding weeks, and included 361 which were referred to the principal epidemic diseases, against 504 and 425 in the two previous weeks; of these 361 deaths, 123 resulted from diarrhœa, 101 from measles, 46 from diphtheria, 32 from whooping-cough, 30 from scarlet fever, and 29 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the 77 towns last week was equal to 1·1 per 1000, against 1·6 and 1·3 in the two previous weeks. No death from any of these diseases was registered last week in Walthamstow, South Shields, Stockport, Hornsey, Huddersfield, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·5 in Barrow-in-Furness, 2·9 in Stockton-on-Tees, 3·2 in St. Helens, and 3·6 in Brighton. The deaths attributed to diarrhœa in the 77 towns, which had declined in the nine preceding weeks from 527 to 184, further fell last week to 123, and were lower than in any week since the middle of August; the highest annual rates from this cause in the 77 towns last week were 1·4 in Oldham, 1·6 in Brighton, and 2·4 in York. The fatal cases of measles, which had been 75 and 107 in the two previous weeks, declined again last week to 101; they caused the highest annual rates, 1·6 in Brighton and in St. Helens, and 1·8 in Tynemouth. The 46 deaths referred to diphtheria showed a further increase of 4 upon the numbers in recent weeks, and included 9 in London and its suburban districts, 3 in Stoke-on-Trent, 4 in Liverpool, 3 in Leeds, and 2 each in Birmingham, Derby, Birkenhead, Manchester, Burnley, Sheffield, and Hull. The 32 fatal cases of whooping-cough showed a further decline from recent weekly numbers, but caused an annual rate equal to 1·9 in Stockton-on-Tees. The deaths from scarlet fever, which had been 26 and 27 in the two preceding weeks, further rose last week to 30, of which 6 occurred in Liverpool and 3 each in Birmingham, Manchester, and Leeds. The 29 deaths referred to enteric fever were within one of the number in the previous week, and included 3 in Manchester and in Bradford, and 2 each in Portsmouth, Stoke-on-Trent, and Rhondda. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily increased in the 11 preceding weeks from 1423 to 1847, had further risen to 1856 on Saturday last; 188 new cases of this disease were admitted to these hospitals during last week, against 234, 231, and 221 in the three preceding weeks. The 1226 deaths from all causes in London last week included 246 which were referred to pneumonia and other diseases of the respiratory system, against 162, 194, and 234 in the three preceding weeks, but were 17 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 33, or 0·8 per cent., of the deaths registered during last week in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Salford, and in 50 other smaller towns; the 33 uncertified causes of death in the 77 towns included 7 in Liverpool, and 2 each in Manchester, Nottingham, Sheffield, and South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 796 births and 492 deaths were registered during the week ending Nov. 5th. The annual rate of mortality in these towns, which had been equal to 13·0 and 12·7 per 1000 in the two preceding weeks, rose to 13·6 in the week under notice. During the first five weeks of the current quarter the death-rate in these eight towns averaged 13·3 per 1000, and exceeded by 0·3 the mean rate during the same period in the 77 largest English towns. The annual

[3] Ibid., No. 31. Price 5d.
[4] Ibid., No. 29. Price 3d.

death-rates in the eight Scotch towns last week ranged from 8·4 and 9·9 in Perth and Greenock, to 14·4 in Leith and 16·6 in Dundee. The 492 deaths from all causes in the eight towns last week showed an increase of 32 upon the number in the previous week, and included 56 which were referred to the principal epidemic diseases, against 63, 47, and 48 in the three preceding weeks; of these 56 deaths, 23 resulted from diarrhœa, 16 from diphtheria, 7 from whooping-cough, 6 from scarlet fever, 3 from "fever," and 1 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·5 per 1000, and exceeded by 0·4 the rate from the same diseases in the 77 English towns. The deaths attributed to diarrhœa in the Scotch towns, which had declined in the five preceding weeks from 51 to 25, further fell last week to 23; they included 8 in Dundee, 6 in Glasgow, 5 in Edinburgh, and 2 in Leith. The 16 deaths referred to diphtheria exceeded the number in the previous week by 9; 7 occurred in Glasgow, 6 in Dundee, and 2 in Edinburgh. The 7 fatal cases of whooping-cough all of which were recorded in Glasgow, showed a slight increase upon recent weekly numbers. Of the 6 deaths from scarlet fever, 3 were returned in Glasgow. The 3 deaths referred to "fever" corresponded with the number in the previous week, and included 2 from enteric fever in Glasgow and 1 of cerebro-spinal fever in Dundee. The fatal case of measles occurred in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 80 and 72 in the two preceding weeks, rose to 84 last week, but were 24 below the number in the corresponding week of last year. The causes of 17, or 3·5 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,799 persons, 564 births and 334 deaths were registered during the week ending Nov. 5th. The mean annual rate of mortality in these towns, which had been equal to 16·9, 17·4, and 16·8 per 1000 in the three preceding weeks, declined to 15·1 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these Irish towns averaged 16·4 per 1000; the mean rate during the same period did not exceed 13·0 in the 77 largest English towns and 13·3 in the eight principal Scotch towns. The annual death-rate during last week was equal to 18·1 in Dublin (against 13·1 in London), 14·4 in Belfast, 11·0 in Cork, 10·8 in Londonderry, 23·2 in Limerick, and 7·8 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns did not exceed 12·4 per 1000. The 334 deaths from all causes in the 22 town districts last week showed a further decline of 38 from the numbers in the two preceding weeks, and included 28 which were referred to the principal epidemic diseases, against 42 and 33 in the two preceding weeks; these 28 deaths were equal to an annual rate of 1·3 per 1000, the rate from the same diseases last week being 1·1 in the 77 English towns and 1·5 in the eight Scotch towns. The 28 deaths from these epidemic diseases in the Irish towns last week included 14 from diarrhœa, 4 from measles, 4 from scarlet fever, 3 from diphtheria, 2 from "fever," and 1 from whooping-cough, but not one from small-pox. The deaths attributed to diarrhœa, which had been 20 in each of the two preceding weeks, declined last week to 14, of which 5 occurred in Dublin and 6 in Belfast. The 4 fatal cases of measles included 3 in Belfast; and of the 4 deaths from scarlet fever, 3 occurred in Dublin and 1 in Belfast. The 3 deaths from diphtheria corresponded with the number in the previous week. A fatal case both of typhus and enteric fever was registered in Dublin. The deaths in the 22 towns last week included 60 which were referred to pneumonia and other diseases of the respiratory system, against 63 and 66 in the two preceding weeks. The causes of 11, or 3·3 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·8 per cent., while in the eight Scotch towns it was equal to 3·4 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon: G. A. Dreaper to the *Hawke* for voyage out, and to the *Hermes*, on recommissioning. Staff-Surgeon: R. H. Mornement to the *Eclipse*, on recommissioning. Surgeons: D. D. Turner to the *Hawke*, for voyage out, and to the *Hermes*, on recommissioning; D G. Addison-Scott to the *Imogene*, additional, and on recommissioning; C. R. M. Baker to the *Pomone*, additional, for Dartmouth College; J. H. Wright to the *Antelope;* and W. C. B. Smith to be lent temporarily to R.M. Division, Portsmouth.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant William M. Browne to be Captain (dated August 1st, 1910). Lieutenant John H. Bell is confirmed in his rank.

ROYAL ARMY MEDICAL CORPS.

Colonel J. C. Culling, on arrival home from Bermuda, has been appointed Administrative Medical Officer of the Western Command. Lieutenant-Colonel J. Maher has been transferred from Potchefstroom to Wynberg and appointed to the medical charge of the military hospital. Lieutenant-Colonel J. M. Irwin, from Woolwich, has joined for duty at Tientsin and taken over the appointment as Senior Medical Officer to the Forces in North China, vice Major A. C. Fox. Lieutenant-Colonel S. G. Allen, recruiting medical officer, London District, has embarked for a tour of duty at Gibraltar. Lieutenant-Colonel J. J. Russell has taken up the duties of Staff Officer to the Principal Medical Officer of the Southern Command in place of Major G. B. Stanistreet, whose tenure of appointment has expired. An exchange of stations in India has been sanctioned by the War Office between Lieutenant-Colonel G. E. Hale, D.S.O., and Major W. W. O. Beveridge, D.S.O. Major W. P. Gwynn has been appointed Embarkation Medical Officer at Karachi for the trooping season of 1910–11. Major B. J. Innis has been granted leave on private affairs from Nov. 7th to Dec. 26th, with permission to travel in the West Indies. Major E. A. Burnside, from Tidworth Park, has been posted to Golden Hill. Major E. G. Browne has embarked for a tour of service in India from the Dublin District. Major B. W. Longhurst, from Warley, has taken up duty at Ashton. Major F. J. Wade-Brown, from Cork, has been posted to Kilworth Camp. Major E. S. Clark has been transferred from Ballykinler Camp to Belfast. Major J. McD. McCarthy has joined at Chester from Chapel Bay Camp. Major J. B. Anderson, from the London District, has been appointed Embarkation Medical Officer at Southampton. Captain C. A. J. A. Balck has been selected for appointment as Specialist in Physical Training for the Irish Command and posted to the Curragh Camp, vice Captain H. A. Davidson, who reverts to ordinary duty. Captain C. S. Smith, from Mullingar, has been posted to Donard Camp. Captain J. T. McEntire, from Chilwell Camp, has joined at Newcastle. Captain H. F. Shea has left the London District for a tour of service in India. The following officers, on conclusion of their course of instruction for promotion at the Royal Army Medical College, have been posted as follows: Captain W. L. Steele to Tidworth Park, Captain W. Riach to the London District, Captain A. R. C. Parsons to the Scottish Command, Captain J. H. R. Winder to Shorncliffe, and Captain D. L Harding to Belfast. Captain E. M. O'Neill has been transferred from Jhansi to Nowgong. Captain B. A. Craig has arrived home on leave from Hong-Kong. Lieutenant J. C. L. Hingston, from Tidworth Park, has embarked for service in India. Lieutenant F. H. Somers-Gardner, from Hilsen, has joined for duty at Cosham.

INDIAN MEDICAL SERVICE.

Colonel J. A. Cunningham, civil surgeon of Lahore, has been selected for the appointment of Inspector-General of Civil Hospitals in the Central Provinces in succession to Colonel P. A. Weir, who has completed the tenure of his appointment. Lieutenant-Colonel J. R Adie, civil surgeon of Ferozopore, has been placed on special duty in connexion with the investigation of antimalarial measures in the Punjab. Major F. O'Kinealy, civil surgeon of Simla, has arrived home from India preparatory to taking up his

appointment as Surgeon on the staff of H.E. the Viceroy-elect of India. Major G. Lamb, Bombay, has been granted four months' extension of his leave on medical certificate. Major G. Hutcheson, on completion of a special course of instruction at the Central Research Institute, Kasauli, has been posted as Civil Surgeon to Aligarh. Captain C. Dykes has received an extension of his leave home from India. The services of Captain W. Lapsley have been placed at the disposal of the Government of the United Provinces. Captain G. Holroyd, Captain A. W. Greig, Captain W. M. Houston, and Captain C. E. Southon, Bombay, have arrived home on leave from India. Captain S. R. Christophers has been appointed Assistant to the Director of the Central Research Institute at Kasauli. Captain W. S. Patton and Captain T. H. Gloster have been appointed to the Bacteriological Department. The services of Captain S. B. Mehta have been placed by the Commander-in-Chief at the disposal of the Government of India for employment at Amritsar. Captain J. W. Little has been granted eight months' combined leave home from India. Lieutenant J. A. Shorten has been appointed Specialist in Radiography and Electrical Science to the Second (Rawal Pindi) Division.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st East Anglian Field Ambulance, Royal Army Medical Corps: Lieutenant Octavius Roberts Ennion, from the list of officers attached to units other than medical units, to be Lieutenant (dated Oct. 3rd, 1910).

2nd Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant David Shannon to be Captain (dated Sept. 15th, 1910).

Attached to Units other than Medical Units.—Lieutenant-Colonel and Honorary Surgeon-Colonel James B. Ronaldson resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Nov. 9th, 1910).

For attachment to Units other than Medical Units.—Jacob Frederick Farrow to be Lieutenant (dated Sept. 6th, 1910).

DEATHS IN THE SERVICES.

Brigade-Surgeon J. M'Neill Beatty, A.M.D. (retired), on Oct. 27th, aged 82 years. He entered the service in 1854 as assistant surgeon and became surgeon in 1867, retiring with the honorary rank of brigade surgeon in 1880.

Deputy Surgeon-General C. Graves Irwin, late Army Medical Staff, on Oct. 23rd, aged 79 years. He joined the service in 1854, becoming surgeon in 1863, surgeon-major in 1873, brigade-surgeon in 1880, and Deputy Surgeon-General in 1884, retiring in 1891. He served in the Eastern campaign of 1854–55, and was present at the battle of the Alma and at the siege and fall of Sevastopol (medal with two clasps and the Turkish medal).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

Among the papers in the November issue of the *Journal of the Royal Army Medical Corps* is one by Colonel Sir David Bruce, C.B., F.R.S., Captain A. E. Hamerton, D.S.O., R.A.M.C., Captain H. R Bateman, R.A.M.C., and Captain F. P. Mackie, I.M.S., on "Muhinyo,"[1] a disease of the natives of Uganda, which has its principal focus along the eastern shore of Lake Albert Edward. The disease is characterised by fever, profuse sweating, pain in the joints and along the course of nerves, swelling of the various joints, especially the ankles, and extreme weakness and emaciation. The writers conclude (1) that "Muhinyo" is Malta fever, and (2) that it is conveyed from the goat to man by the drinking of goat's milk. The Medical History of the South African War is continued by Lieutenant-Colonel R. J. S. Simpson, C.M.G., R.A.M.C., and Recruiting in the German Army is the subject of a paper by Captain J. A. Black, R.A.M.C.

"Audi alteram partem."

THE ECONOMIC ASPECT OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—I have to thank you for your kind and appreciative notice of my annual report which appeared in THE LANCET of August 13th. In that report I endeavoured to show that an expenditure of £500 not only makes 24 men wage-earners for nine months and postpones and diminishes their chargeableness to the guardians in that time, but it also makes eight men permanent wage-earners and saves an expense from the rates within the next ten years of £1820. This conclusion you criticised on the ground that there was not sufficient evidence to show what would have happened to the wage-earners if they had not gone to the sanatorium. As you say, all depends upon the nature of the cases on admission. In order to test the justification of your criticism I have been at some pains to find out what has occurred in notified cases of consumption who did not go to the sanatorium. This inquiry has taken some time, hence the delay in sending this letter.

I have endeavoured to follow up 278 cases who were notified in the years 1905–06, cases which went to the Peppard Sanatorium being excluded. To make this class of notified cases comparable with the cases which went to Peppard Sanatorium it is desirable also to deduct all cases which died within three months of notification, for most of such would no doubt have been considered unsuitable for sanatorium treatment. There were 88 who died within three months. This leaves 190 notified cases who did not go to the sanatorium but lived three months after notification. Of these it was found on inquiry in October that 100 had died and 16 were still alive, leaving 74 who could not be traced. Assuming that the proportion of dead and alive among the 74 is as 100 to 16, we have an estimated total of 164 dead and 26 alive. Thus 14 per cent. of the notified cases are estimated to be alive. Taking now the Peppard Sanatorium cases in the same years 1905–06 we find there were 50 notified cases, of whom 21 are known to be alive and 22 dead. Of the 7 unaccounted for several went to Canada and are probably living there. Estimating that 25 are alive we have 50 per cent. of sanatorium cases alive compared with 14 per cent. of other notified cases. I think this result justifies, to a large extent, my statement that most of the men who went to the Peppard Sanatorium would have died within two or three years but for the sanatorium. It is true a certain amount of selection is exercised in sending cases to the sanatorium. No case is sent which appears likely to die within three months' time. Febrile cases are sent if, after a rest of a few days in bed, their evening temperature is below 100°. Cases are not sent when they have advanced disease affecting three lobes on one side of the chest, nor advanced disease affecting one lobe on each side; but cases are sent with fairly advanced disease on both sides. Practically no men have been sent to the sanatorium who were capable of work at the time they were sent. In the large majority of cases work had been discontinued. In a few cases, though work had not been discontinued, it was highly desirable that it should be. One case had been discharged from the dockyard, and many others would have been discharged from work in the arsenal except for the prospect that sanatorium treatment would enable them to resume work. Among those who did not go to the sanatorium, although there were a certain number of cases too advanced for admission, there were, on the other hand, many cases of mistaken diagnosis, whereas all the cases found not to be tuberculous were excluded from the sanatorium cases. It must be remembered also that many who did not go to Peppard Sanatorium went to some other sanatorium, and many of those who went to the workhouse infirmary had the advantage of open-air treatment there.

The Woolwich cases are sent to Peppard in the first instance for one month only. Very few stay as long as six months, and none longer, unless they become "working patients" and maintain themselves at the sanatorium. This

arrangement enables patients to be discharged if it is found that they are not likely to benefit at the sanatorium, and encourages the sending of more advanced cases than would be sent if there were a fixed duration of stay of from 3 to 6 months. The average duration of stay in 1909 was 2½ months. It is, as you point out, difficult to give figures which absolutely prove the benefit of sanatorium treatment, but although experience shows the limitations of this treatment it also more and more convinces me of its decided advantages.—I am, Sir, yours faithfully,

SIDNEY DAVIES, M.D. Oxon.,
Medical Officer of Health of Woolwich.

Nov. 3rd, 1910.

ACUTE ANTERIOR POLIOMYELITIS AFTER BATHING.

To the Editor of THE LANCET.

SIR,—I have read with interest the records of two cases published in THE LANCET of Oct. 8th, p. 1083, by Mr. C. R. Sutherland and Dr. W. Robinson, in which paralysis, regarded as acute anterior poliomyelitis, developed in two brothers after bathing in the river Wear. Three years ago I saw in consultation a case of paralysis of all four limbs which presented the clinical features of acute anterior poliomyelitis, and terminated fatally. The boy had spent two hours in the water in a public swimming bath in Manchester one September afternoon. Next day he was unwell, and was never able to attend school afterwards. At first there were slight febrile symptoms and headache, suggesting commencing meningitis; but at the end of a week paralysis of both legs developed, the knee-jerks and tendo Achillis reflexes were lost, the arms and intercostals became paralysed a few days later, and death occurred from respiratory paralysis. There was no anæsthesia, and the bladder and rectum were not affected. Though no necropsy was obtained, I have no doubt the case was one of acute anterior poliomyelitis. A school friend of this boy was with him at the swimming bath and spent about the same time in the water. He also was unwell from that time. I did not see this case, but he died the day after the patient whose history I have just briefly recorded. A definite diagnosis had not been made, but I have heard that the symptoms pointed to an acute affection of the nervous system.

Twenty years ago I recorded a case of acute anterior poliomyelitis in a young adult. His illness directly followed a visit to a public swimming bath, and the patient regarded this as the cause of his paralysis; but at that time I regarded it as a mere coincidence. The disease terminated fatally. I examined the spinal cord microscopically and found the typical changes of acute anterior poliomyelitis. Allen Starr states in his book, "Organic Nervous Diseases" (London, 1903), that he has seen "several children who were attacked with infantile spinal paralysis subsequent to long-continued bathing in cold water during the summer." Much light has been thrown on the etiology and pathology of acute anterior poliomyelitis by observations during the recent epidemics of the disease in Norway, Sweden, Germany, and America, and by the recent experiments on animals (Landsteiner and Popper, Flexner and Lewis, and others), which have clearly proved that the disease can be transmitted to monkeys by the injection of an emulsion of the diseased human spinal cord. From the experiments and observations of Landsteiner and Levaditi, and of Flexner and Lewis, and others, it appears probable that the poison is transmitted by the salivary and nasal secretions, and that it enters the system through the mucous membrane of the nose, fauces, and alimentary canal. Much is still obscure, however, with regard to the exact cause of the disease. Of course, it is only in very rare cases that the disease has followed bathing, but such cases are worthy of careful investigation in the future. It is possible that a poison in the water may enter the system through the nose or fauces whilst bathing, or that the long exposure of the system to cold may lower its resisting power and make it more susceptible to the action of micro-organisms; but it appears very improbable that in the few cases on record the development of the disease after bathing has been a mere coincidence.

I am, Sir, yours faithfully,

Manchester, Nov. 8th, 1910. R. T. WILLIAMSON.

EFFICIENT VENTILATION.

To the Editor of THE LANCET.

SIR,—If Dr. Th. Glover Lyon would be good enough to repeat his experiment of entertaining his 20 guests in a room 20 feet by 15 feet by 10 feet, and will observe the wet bulb when he cuts off the air-supply, and then cool the air in the room instead of replenishing the air, he would find, I think, that the discomfort of his guests varies with the wet-bulb temperature, and has nothing to do with the chemical purity of the air. Before taking refuge in his hypothetical "spiral toxes" we must eliminate, I think, the potent cause of our discomfort—a high wet-bulb temperature. This is particularly uncomfortable to one who has his temperature sense organs adapted to a cooler atmosphere. It is, I believe, owing to the curious "adaptation" of the temperature sense organs that we are so struck with the unpleasantness of hot crowded rooms when coming into them from fresh air. When "set" for warmth we do not like a draught of cold air, when "set" for cool air we do not like warm moist air. Not only do the temperature sense organs adapt themselves to the surroundings, but the olfactory sense quickly fatigues; thus the sewer man does not notice the smell after a few minutes in the sewer, neither do the guests in a crowded room. There is very great relief to be had from fans in conditions where pure air cannot be obtained, and I would urge most strongly this simple means on all who cannot instal expensive and often useless systems of ventilation. The point I insist on, following in the steps of Dr. John Haldane, is that our efforts should be directed towards keeping down the wet-bulb temperature. A good ventilation, of course, brings down the wet-bulb temperature. Until the heat factor has been eliminated we have no right to talk of mysterious poisons in the air of crowded rooms, for the unpleasant skin sensations arising from hot moist air have a most profound effect on our mental well-being. I agree with Dr. John Haldane that the wet-bulb temperature should not be allowed to exceed 70°–75° F. for the comfort of workers to be secured. Cool air is, I venture to maintain, more important than chemically pure air in our dwellings and factories.

I am, Sir, yours faithfully,

LEONARD HILL.

London Hospital Medical College, Nov. 8th, 1910.

FIRST OPERATION UNDER ETHER.

To the Editor of THE LANCET.

SIR,—I am much obliged for your reference to the *Pharmaceutical Journal* for a report of the above, but the house surgeon, Mr. Ransome, incorrectly reported the date. Through the courtesy of the Surgical Registrar of University College Hospital I have had the pleasure of reading the complete notes on the case of Churchill. These notes are full and taken on consecutive days. The day of the operation was Monday, Dec. 21st, 1846. It was on Saturday, Dec. 19th, that Dr. Boot wrote to Liston as to the success of the anæsthesia produced by ether. On that day Mr. Robertson, a dentist, removed some teeth, having previously administered ether (see Buxton's "Anæsthetics"). Dr. Boot immediately wrote to Liston, sending him at the same time the account from America, and he at once called on his friend Peter Squire, the chemist in Oxford-street, saying, "You must fix up something so that we can try this as soon as possible." This was told me by Mr. Squire's son, to whom his father had often repeated the tale. I have heard from two surviving witnesses of the operation, and one of them is clearly of opinion that the day "was a Monday in December." I think the mistake is quite easily understood. The surgeon's visiting days in Ward 1 have always been Mondays, Wednesdays, and Fridays. It is easy for a busy man to forget which was the one when writing from memory, even if it is only a few days after. I am, Sir, yours faithfully,

F. WILLIAM COCK.

Porchester Houses, Porchester-square, W., Nov. 3rd, 1910.

*** In the *Pharmaceutical Journal*, Vol. VI., No. 8, Feb. 1st, 1847, p. 350, Mr. Squire himself published an account of the apparatus constructed by him for the inhalation of the vapour of ether. At the beginning of that article he refers to "the temporary apparatus which I put

hastily together for Mr. Liston when he performed the first capital operation in this country without a sign even of pain." Illustrations of the apparatus are also published in the same place. Dr. Francis Boott (the London Medical Directory for 1846 misprinted his name as "Francis Booth." His name was really Boott) communicated to THE LANCET of Jan. 2nd, 1847, p. 5 *et seq.*, copies of papers and letters relating to "Surgical Operations Performed During Insensibility." In Dr. Boott's letter, on p. 8, he mentions the extraction of a tooth on Dec. 19th, 1846, by a Mr. Robinson (not *Robertson*), and he also includes a copy of a letter from Mr. Robert Liston to himself, which is dated Dec. 21st, 1846, and commences "I tried the ether inhalation to-day in a case of amputation of the thigh, and in another requiring evulsion of both sides of the great toe-nail.' This confirms Dr. Cock's supposition that Mr. Ransome, the house surgeon, gave the date of the operation wrongly as "Friday, December 18th, 1846, at 2 o'clock."—ED. L.

THE LONDON COUNTY COUNCIL AND MEDICAL FEES FOR SCHOOL ACCIDENTS.

To the Editor of THE LANCET.

SIR,—I have to inform you that the Council has recently had under consideration the question of fees to be paid for the first medical attendance on children who meet with accidents in public elementary schools, and has adopted the following scale, which will come into operation as from 1st December, 1910:—

(*a*) In the case of a child who meets with an accident in the school and who is taken to a doctor's surgery, 3*s*. 6*d*.

(*b*) In the case where a doctor is summoned to the school to attend a child, 5*s*.

Claims in excess of these amounts will, if there are exceptional circumstances, receive special consideration. These fees will be paid by the Council for the first attendance only.

I am, Sir, your obedient servant,

G. L. GOMME,
Clerk of the Council.

County Hall, Spring gardens, S.W., Nov. 9th, 1910.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Crematorium.

IT is now eight years since the Manchester Crematorium was opened, and during this period 1428 cremations have taken place. In the 12 months ending on August 31st last there were 110 cremations. Some of the subjects were from Manchester and the neighbourhood, but 15 places outside Manchester helped to make up the total. Among these were several of the Lancashire towns and places so far distant as Edinburgh, Penmaenmawr, Macclesfield, Stoke-on-Trent, Aysgarth in Yorkshire, and others. The directors in the annual report urge the need for propaganda in favour of cremation—"as there is still a considerable amount of prejudice and indifference to be overcome." In the course of his speech, Mr. Gustav Eckhard, presiding at the annual meeting of the Manchester Crematorium, Limited, mentioned the fact that many famous men had been cremated during the last 12 months, and touched also on the religious question connected with cremation. He combated the notion that it was an irreverent method of disposing of the dead, and said that "three successive holders of the see of Manchester—Bishops Fraser, Moorhouse, and Knox—had expressed themselves in favour of cremation as a means of disposal of the dead. There are, no doubt, advantages and disadvantages in all modes of putting the dead out of our sight, but in the case of pestilence, infection, or the slaughter of the battlefield, there is no better method of dealing with human remains than that of cremation. Still, there does exist a sentiment, not easily to be overcome, in favour of earth burial, and it will linger as long as England has country churchyards.

A Slot Meter Danger.

Penny-in-the-slot gas-meters are much used by the working classes in our large towns, and usually without accident. A few days ago, however, four children at Stockport had a narrow escape from being asphyxiated from one being used. During the night the supply of gas became exhausted and one of the daughters, before going to work in the morning, put a penny in the slot, not knowing that a light had been left burning in the room where the children were sleeping. The light having gone out, the gas of course escaped into the room, and when the occurrence was discovered, owing to the moaning of the children, they were found to be unconscious. One had to be taken to the infirmary, but happily all recovered in the course of a few hours. It is, perhaps, a wonder that such an accident is not of more frequent occurrence where a penny is put into the "slot" or gas turned on at the meter. At all events, it points to the desirability of seeing to it that no gas taps are left turned on.

Treating Consumption.

The old Chorlton Union Board of Guardians is now called the South Manchester Township Board, and the subject of provision for consumptive cases came under discussion at the last meeting. The board seems to be in earnest as to building a sanatorium, the chairman saying that as the result of advertising numerous sites could be obtained. A letter was read from the sanitary committee of the city council, suggesting an interview with the board on the subject of the treatment of consumptive cases. The feeling on the board seemed to be in favour of proceeding with its own scheme, whatever the corporation might do, as its own efforts and the corporation's would not for a long period meet the demand. There are said to be 5000 or even 6000 cases in Manchester supposed to be curable, the provision for which may well tax all the efforts of the guardians, the corporation, and of private benevolence to deal with, more especially if it is remembered that the father or the mother of the family may be the victim. One of the medical members of the board remarked that "the guardians must deal with the poor, for the corporation would only deal with the lower middle or upper working classes."

The Asylum Difficulty.

The crowded state of the asylums and the consequent detention of dangerous lunatics in workhouses where there is no suitable or sufficient provision for the safe care of such patients is often a topic at meetings of our boards of guardians. At the last meeting of the Prestwich board the clerk drew attention to this "vexed problem of long standing." There were at the time two men in the workhouse certified as fit cases for the asylum, and one of them had just committed two assaults. He (the clerk) had written to the authorities at Winwick, Lancaster, and Prestwich, and the reply from each had been that there was no room for additional male patients. He said "it was a most serious matter, and the workhouse master was having an anxious time of it." The clerk was instructed to write to the Asylums Board in the strongest possible terms in regard to the difficulty. The increase of insanity is a grave national danger.

Cotton Districts Convalescent Fund.

The annual meeting of the governors of the above-named fund, reminding many of the hard times of the Lancashire cotton famine resulting from the American war of North and South, was held on Oct. 28th. Its work, begun nearly 40 years ago, still goes on, for during the nine months ending Sept. 30th 1512 patients were sent to the convalescent hospitals at Southport, Buxton, and Cheadle at a cost of £4209. In the corresponding period of last year 2374 patients were sent at a cost of £4093.

Nov. 8th.

UNIVERSITY OF SHEFFIELD.—The Council at its last meeting appointed Mr. Archibald W. Cuff, F.R.C.S. Eng., to the post of Lecturer on Practical Surgery.

NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The Chapel in the Royal Infirmary.

REFERENCE has been made in these columns to the controversy connected with the chapel in the Royal Victoria Infirmary in this city.[1] It may be remembered that, when the new infirmary was erected a few years ago, a chapel was constructed for the institution. This, no doubt, was done following the precedent of the presence of a chapel in the old infirmary from its beginning. This new chapel was consecrated as a Church of England edifice, and enjoyed a brief usage for the ordinary services in vogue in the institution. Other denominations wishing to hold services in the infirmary were allowed the use of the lecture theatre for the purpose. After some little time the question arose as to whether Nonconformists could not have equal rights to conduct their own particular services in the chapel (St. Luke's). After much expenditure of time, talk, and several governors' meetings, and when it had been decided by expert opinion that it would be illegal to use the chapel for Nonconformist services, the entire closure of the edifice was voted at a governors' meeting in February, 1908. On August 27th of this year the quarterly court of governors passed a resolution rescinding the closure of the chapel and "instructing the house committee to reopen St. Luke's Chapel for religious services and to provide facilities for Anglican, Free Church, and such other services as may be required in the interests of patients and staff." The house committee meeting on Sept. 22nd discussed the situation at length, Sir George Hare Philipson presiding. It was eventually resolved that the committee could not carry out the order given at the court in August. The reason for this attitude is found in the opinion of the infirmary's legal advisers that any governor could easily get an injunction against the house committee should they carry out the governors' instructions, and that the cost of such injunction would have to be paid by members of the house committee personally; and further that refusal of members to pay such costs, or, in case of the house committee, refusing to obey the injunction the members might be imprisoned for contempt of court.

The whole situation was discussed again at a special court of governors held on Oct. 22nd, when Sir George Hare Philipson presided. Notice was given previous to the court that Alderman Goolden would move a proposition with a view to settling the difficulty :—

> That a separate chapel be erected and equipped for the use of Nonconformists, and that it be paid for out of the same funds as St. Luke's Chapel was built out of, and that the amount to be so expended shall be similar, if necessary, to the sum paid for the erection and equipment of St. Luke's Chapel.

The result was a stormy meeting, several amendments having been put down on the agenda. In order to clear the way Alderman Goolden withdrew the motion standing in his name in favour of the first amendment, proposed by the Lord Mayor, Sir William Stephenson, who suggested that the question as to the validity of the consecration as an Anglican edifice be settled by the High Court of Justice. He deprecated the continuance of the controversy and wished to get the matter settled once and for all; the cost of this process would be £200 or £300, and in reply to an interruption he said he would settle the bill himself if no one else did. This amendment was carried after opposition, and a committee was appointed to take the question to the High Court.

The account of these proceedings cannot be very edifying to the outside public, especially to that portion which helps voluntary institutions by its support, and no doubt such a public, whatever its individual creed, would prefer a secular hospital to one in which religion has induced so much controversy. There is a large section of the community here which cannot see the necessity for a chapel at all in the infirmary. The average stay of patients is not long, the pressure on the beds is great, and in the vast majority of cases when the patient is well enough to attend services he is well enough to go home, and wants to do so. The opinion of the public is varied: first, as to the wisdom of the house committee in allowing a considerable sum (it is believed about £3000 or £4000) to be spent on a chapel; secondly, in having it consecrated in the Anglican Church, thereby preventing its use by any other denominations; and thirdly, as to the entirely altruistic attitude of the general court of governors concerning religious equality. Many fear that the attitude has been adopted in view of the large proportion of the funds subscribed by the working man. It is to be feared that the working man, as distinct from the poor man, has forgotten the purpose for which the infirmary was built—to relieve the sick and lame poor—and now looks upon his penny and twopence a week as paid in support of a provident institution, to which he contributes and from which he expects to receive return. While the £16,000 contributed last year by the workmen is highly creditable to the subscribers, each man is apt to forget that he and his fellow workers have not contributed to the endowments to the building, which have been from time to time made by charitable people in legacies and gifts. Further, it may be asked if you build a chapel for Nonconformists what are you going to do for the Roman Catholic or for the Hebrew? One speculates as to the appearance of the hospital when it is surrounded by all sorts of little chapels dotted about its grounds, to say nothing of the expense of such a process. The independent and impartial observer, who cuts himself off from all parties and creeds while he forms his judgments, will wish heartily that the matter may be finally closed by the decision of the courts—and if a peaceful solution be not thus reached he would be glad if the chapel might remain closed, or even got rid of altogether.

Nov. 8th.

[1] THE LANCET, March 20th, 1909.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The Treatment of Consumption in Bristol.

THE Bristol board of guardians has, after several animated discussions, rejected the proposition to buy an estate in Somersetshire, a few miles out of Bristol, for the purpose of equipping it as a sanatorium for paupers suffering from pulmonary tuberculosis. The alternative plan—namely, development of their premises at Southmead, which are already chiefly used for the treatment of phthisis—has been adopted, and a subcommittee appointed to consider ways and means.

Vaccination by the Bristol Board of Guardians.

The latest vaccination returns issued by the Bristol board of guardians show that vaccination is still decreasing. For the year ended Sept. 30th, 1910, 2514 primary vaccinations were performed at the expense of the poor-rates, compared with 3081 for the corresponding period of 1909.

The Bristol Medical School.

The annual dinner will take place on Nov. 29th, at the Royal Hotel, College Green, at 7.30 P.M. Mr. James Taylor is president and the guest of the evening will be Sir Alfred Keogh, retired Director-General, Army Medical Staff.

Medical Service at Torquay.

On Sunday afternoon, Oct. 23rd, a special service for medical men and nurses was held at St. Luke's, Torquay. There was a large congregation, which included about 30 members of the medical and 50 of the nursing professions. The sermon was preached by the vicar (the Ven. A. H. Simms, Archdeacon of Totnes), who in the course of an eloquent address alluded to the work of the priest and physician, and showed how both should work together for the sick and suffering.

The West of England Eye Infirmary, Exeter.

The annual meeting of the subscribers to the West of England Eye Infirmary was held on Oct. 28th. The medical report stated that during the past 12 months 3710 patients had been treated. The daily average number of in-patients was 42. The financial statement was satisfactory. The committee alludes to the completion of the new wing which was erected to commemorate the centenary of the institution.

It was formally opened, free from debt, by Earl Fortescue on Sept. 21st last.

The Yeatman Hospital, Sherborne.

The proprietor of a travelling bioscope entertainment, named Rowland, has been made a life-governor of the Yeatman Hospital, Sherborne (Dorset), in recognition of his financial assistance to the institution. By means of "benefit nights" Mr. Rowland has during the past few years received £116 for the hospital funds.

Nov. 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

General Council of the University of Edinburgh.

THE statutory half-yearly meeting of the Edinburgh University General Council was held on Friday, Oct. 28th. The meeting had the unusual distinction of being presided over by the Lord Chancellor of the University, the Right Hon. A. J. Balfour, M.P. In the report of the Business Committee reference was made to the fact that the Treasury, acting on the advice of Lord Elgin's Committee, were to make an additional grant of £40,000 per annum to the Scottish universities, of which sum £12,500 would come to the University of Edinburgh. The report of the sub-committee on Draft Ordinance (regulations for degrees in medicine) was also submitted. The report approved generally of the terms of the Draft Ordinance and regarded it as an important step in the direction of the autonomy of the universities which the General Council of the University of Edinburgh had long been contending for. The important provisions were those which gave the University power to introduce from time to time reforms in the medical curriculum without the delays and difficulties which were attendant upon procuring a new ordinance on every occasion on which the progress of medical science and teaching seemed to require some modification of the curriculum. With this preliminary expression of approval all who are interested in the maintenance of the position of Edinburgh as a great medical school will wholly agree. One very important proposal in the report was that certain words should be deleted from the Draft Ordinance. The deletion of the words meant that instruction in the subjects of the first professional examination might be received in such schools and science colleges as might be recognised by the University Court, and that such courses of instruction could count although attended prior to registration as a medical student. This was intended to allow the subjects to be passed before the commencement of the medical curriculum. This proposal was submitted by Professor E. A. Schäfer and was opposed by Principal Laurie of the Heriot-Watt College; Professor Schäfer's proposal was carried by 21 to 16. The report next suggests that powers should be taken to impose a limit on the number of students attending any one clinic. No objection was raised to this important suggestion. The committee further suggests that a clause should be added to the Draft Ordinance to the effect that changes, which in the past have been usually arranged by the faculties and Senatus and subsequently approved by the University Court, shall be communicated to the General Council, "and representations made thereon by the General Council within two months from the date of communication shall be taken into consideration by the University Court before any such regulation is approved." The adoption of this report concluded the business. The fact that this report on the Draft Ordinance is signed by the professor of physiology as chairman of the subcommittee which drew it up may be taken as a sign that the University realises more fully than it did that proposals and recommendations issuing from the Business Committee of the General Council have the interests of the University at heart. It is indeed highly desirable that the University should be more sensitive to outside movements and opinions than it sometimes is, and the measure of autonomy which the Draft Ordinance asks for would presumably lead to that. When it is realised that the University has no power even to regulate the size of its clinics it will be also realised how hopeless it is to look for change until freedom is obtained. The University is to be congratulated on asking for that freedom.

Lunacy in Glasgow.

The report of Dr. John Carswell, certifying physician in lunacy to the Glasgow parish council, has just been issued for the past year, and there is a note of optimism about it that is very encouraging. The total number of cases reported to the inspector during the year was 1018. Of these, 553 cases were certified insane. This is 25 less than in the previous year, and is the lowest recorded since the year 1906. But the number of cases certified is not an accurate indication of the occurrence of insanity, for included in that is a number of cases previously certified. Thus last year, of 553 cases certified, only 392 were certified insane for the first time, the remainder having been previously under certificate. The figure 392 therefore represents the true occurrence of insanity in Glasgow parish during the year 1909–10. This is 49 fewer persons than in the previous year, and it is the lowest number since 1906. On an estimated population of 660,713 the number of persons certified insane for the first time represents a production-rate of 56·3 per 100,000, the lowest for the last ten years. During the last ten years the rate has fluctuated between 56·3 per 100,000 last year and 70 per 100,000 in 1902. The average annual rate for the first five years of the decade was 66·6 and for the second five years it was 63·7, a decrease of 2·9 per 100,000. This is similar to what is occurring throughout Scotland. The average annual production-rate for the whole of Scotland was 50 per 100,000 during the five years 1900–04 and it fell to 46 during the years 1905–09. It is worthy of note that the higher production-rate in Glasgow is largely due to the inclusion in the Glasgow record of first cases, of imbecile children, and also of certain Glasgow cases brought from other districts, and by a somewhat lower estimate of population than that used by the Commissioners in Lunacy. Dr. Carswell shows in his report that the decrease has occurred in the young and active sections of the population, between the ages of 15 and 45 years, who should, presumably, be most directly affected by the alleged overpressure of modern industrialism. A slight increase is noted in cases of insanity amongst older people, but this is, in part at least, attributable to the fact that many cases of senile decay are now remitted to asylums instead of being treated elsewhere. In discussing the distribution of the cases, the wards are divided into three groups according to whether the insanity-rate is high, low, or average. It is worthy of note that the wards which had high lunacy-rates had high death-rates, and it may be added that there are about three times as many public-houses relatively to the population in the first set of wards as there are in the second and healthier set. These figures go far to prove that the slum is just as much responsible for insanity as it is for physical deterioration.

Clinical Research Laboratory for Victoria Infirmary, Glasgow.

The Victoria Infirmary, Glasgow, has been put in possession of a handsome gift from an anonymous donor for the purpose of building and equipping a laboratory for clinical research. The gift amounts to £5000. The Western Infirmary, Glasgow, is also adding a laboratory on the same lines.

Infectious Disease in Dundee.

A serious increase in the number of cases of infectious disease occurred in Dundee during October. The total was 395, as against 246 in September and 152 in October of last year. Scarlet fever last month rose from 127 cases to 196, while diphtheria had increased from 53 to 91. Whooping-cough exactly doubled—44, as against 22; while chicken-pox rose from 11 to 41. Typhoid fever and erysipelas were both down. In October of last year there were only 97 cases of scarlet fever and 30 of diphtheria.

Typhoid Fever Outbreak in Strichen.

A serious outbreak of typhoid fever has occurred in the village of Strichen, fully a dozen cases having been notified to the medical authorities. At a meeting of the public health standing subcommittee of the Deer district a report on the matter by the medical officer of health was considered. From this it appears that the majority of the patients had received milk from the same dairy, but the medical officer reported that he had failed to find any source of specific contamination of the milk. He suggested, however, that the dairyman should be asked to try the effect of engaging other employees at the dairy to milk the cows and handle the milk,

and if necessary that new utensils should be provided. The committee considered the evidence as scarcely sufficient to warrant it in stopping the supply of milk from the dairy in question. The suggestions of the medical officer were approved, and he was authorised to make provision for these measures, and such others of a similar kind as might suggest themselves to him, being carried into effect without delay. It was also decided to have a report upon the water and drainage systems of the village.

Northern Infirmary, Inverness.

The half-yearly general meeting of the managers of the Northern Infirmary, Inverness, was held on Nov. 2nd, when the following motion was carried:—

That in view of the revenue account in bank being at present considerably overdrawn, the directors be authorised to withdraw from capital account a sum not exceeding £1000.

Ex-Provost Gossys was cordially thanked for the excellent services rendered by him as chairman during his term of office in the occupancy of the civic chair.

Birth-rate in Aberdeen.

As in other places the birth-rate in Aberdeen is decreasing, and that to a very considerable extent. The population of Aberdeen calculated by the Registrar-General is 185,703 for the present year, and on that basis the birth-rate for the districts of St. Machar and St. Nicholas works out at 16·7 per 1000. It is, however, slightly higher than that, because the population has not grown quite so rapidly recently as between 1891 and 1901, the dates of the two last censuses. The birth-rate has, however, fallen considerably in the last 30 to 40 years, but more particularly in the last 10 to 20 years. In 1866 to 1875 the average birth-rate was 36·2 per 1000 of population, in 1876 to 1885 it was 34·4, in 1886 to 1895 it was 32·2, and in the five years from 1899 to 1903 the birth-rate was 31·2 per 1000, which may be considered pretty accurate, as the present slackening in the growth of the population did not show itself much until after 1903. In the five years 1904 to 1908 it may be taken at 28·5 per 1000, and according to the Registrar-General's estimate the birth-rate for 1909 was 24·8; this, however, for various reasons might be put at 26 per 1000, a figure still very much below the 36·2 of 40 years ago. The reduced birth-rate has not until lately affected the normal increase of the population, because of the coinciding fall in the death-rate. The excess of the birth-rate over the death-rate was in 1866 to 1875 13 2 per 1000 of the population, which represented the normal increase apart from the effects of emigration or immigration. In the five years from 1899 to 1903 the difference between the birth-rate and the death-rate was 13·1; but in 1907 the difference was only 12·2, and in 1908 it was 11·2, while in 1909 it was about 10·7. In his report for 1908 Dr. Matthew Hay worked out the relations of births to marriages to ascertain whether the decline in the birth-rate was due to the diminution in the marriage-rates. He found it was not so. In the period from 1866 to 1875 the average number of births to each marriage was 4·4, which gradually fell to 3·3 in the five years ending 1908.

Stirling Royal Infirmary.

At the annual meeting of the supporters of the Stirling Royal Infirmary it was stated that in response to the appeal made by the directors for the sum of £12,000 for extending the infirmary £8150 had been already promised. The directors have decided to proceed with that part of the extension which involves the erection of the west wing at a cost of £4250. This building is now well advanced, and it is hoped that it will be ready for occupancy by next spring.

Nov. 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mastership of the Rotunda Hospital.

THE Master of the Rotunda Hospital holds office for seven years, and last week Dr. E. Hastings Tweedy, having completed his term, handed over the duties to his successor, Professor Henry Jellett. A few days prior to his leaving the hospital a handsome presentation of a silver tray was made to Dr. Tweedy by the nursing staff and pupil nurses who had been trained under him. The governors of the charity, before electing a successor, passed a warm resolution of thanks to the outgoing Master for "his devoted attention to the patients and to the interests of the charity." During Dr. Tweedy's time at the Rotunda many improvements have been carried out. The lying-in accommodation has been increased; rooms for women students have been provided; a residence wing for nurses has been built, giving room for additional pupil nurses; isolation rooms have been provided; and electric lighting has been introduced. The work of the hospital has largely increased, the maternity patients being more numerous by 500 a year than they were seven years ago. At the same time, in points of technique Dr. Tweedy has kept abreast with modern progress, and his last year in office has the distinction of being the year of lowest morbidity in the history of the hospital. Dr. Tweedy leaves the Rotunda to resume the duties of gynæcologist to Dr. Steevens' Hospital. Dr. Henry Jellett, who last year was elected King's professor of midwifery in the School of Physic, and now succeeds Dr. Tweedy, like his predecessor, possesses indefatigable energy, and the reputation of the hospital is sure to be maintained in his hands.

Notification of Deaths of Persons over 70.

District registrars, who in Ireland are mostly dispensary medical officers, have the duty of furnishing each week to the pensions officers the names of all persons whose deaths at ages over 70 have been registered. For these returns the Lords of the Treasury sanction a fee per name of 2*d*. Some time ago the Irish Medical Association protested against the inadequacy of the fee, but without result. At a recent meeting of the Council of the Association a suggestion was made that a list of names and addresses of Old Age Pensioners in each district should be periodically sent to the registrars, so that when the death of any person on this list is registered the registrar shall furnish a certified copy of the entry to the pensions officer, as is done in the case of navy or army pensioners. If this method were adopted the statutory fee of 2*s*. 7*d*. would be paid for each certificate.

Women Inspectors of Lunatics.

Last week the Blackrock urban council, on the movement of Lady Dockrell, passed the following strong resolutions demanding the appointment of women inspectors of lunatics and women members of asylum committees:—

(1) Having regard to the fact that nearly half the lunatics in Ireland are females, the Government be asked to appoint a lady inspector to visit the female lunatics in Ireland; (2) that having regard to the large number of female lunatics and to the increasing expenditure for the upkeep of the asylums and also for the maintenance of the insane, the Government be asked to make it compulsory that at least one member of every asylum committee in Ireland should be a woman.

Retirement of Sir John Fagan.

Sir John Fagan has retired from the offices of Inspector of Industrial Schools and Member of the General Prisons Board, Ireland. The former post he has held since 1897; to the latter he was appointed a few years ago on the retirement of Sir Stewart Woodhouse. In his earlier days he practised as a surgeon in Belfast. He received the honour of knighthood a few months ago. Surgeon-Colonel Edgar Flinn, medical inspector of the Irish Local Government Board, has been appointed to succeed Sir John Fagan in both capacities.

Health of Belfast.

From a report presented by the medical officer of health at the monthly meeting of the city council held on Nov. 1st, it appears that 121 cases of infectious disease were notified during the month ended Oct. 15th, as compared with 73 in the preceding four weeks, and 99 in the corresponding period of 1909. The increase is due to scarlet fever and diphtheria, of which 68 and 26 were notified respectively as compared with 33 and 11 in the previous month, and 45 and 10 in the corresponding period of 1909. No deaths had occurred from scarlet fever and only two from diphtheria. At present the resources of Purdysburn fever hospital are overstrained, and the health committee on Nov. 1st, at a special meeting, resolved to ask the board of guardians to receive surplus patients. The present accommodation at Purdysburn fever hospital is for 168 patients (they have now 159 in the wards); the proposed extension will take a considerable time to carry into effect and it provides for 268 patients, but, as pointed out by the chairman of the public health committee, they needed (on the principle of one bed for every 1000 of the population) 400 beds. This is precisely what those who gave evidence at the

Belfast Health Commission showed, and it is satisfactory to find that the city council now admit its correctness.

The Queen's University of Belfast.

The following interesting statistics give the total entries in session 1909–10, the first since the foundation of the University. In the faculty of medicine there were 279, of whom 9 were women; in the faculty of arts, 198, of whom 89 were women; in the faculty of science, 120, of whom 25 were women; and in the faculty of law, 11, all men. There were 12 non-matriculated students, 9 of whom were women and 3 men. The total number of students in session 1909–10 was therefore 618.

The King Edward Memorial in Belfast.

The subscriptions to the King Edward Memorial, which is to take the form of an additional block to the Royal Victoria Hospital, now amount to £14,018 10*s.* 6*d.*

University College, Cork: the Conferring of Degrees and the Behaviour of the Students.

On Nov. 3rd the degree Congregation of University College, Cork, assembled in the examination hall of the College. A number of friends of the students, among whom were many ladies, occupied the body of the hall, and the galleries were crowded by the undergraduates. Some of these young gentlemen showed their absolute ignorance of manners. Beginning by throwing down paper darts, they passed to lumps of sugar and thence to pieces of stale herring. One of the lady students, when approaching the platform to have a degree conferred on her, narrowly escaped being struck by such a disgusting missile, which fell on the leg of one of the professors. When the students subject their own friends to such treatment discredit falls upon them for their want of the ordinary sense of hospitality. Cordial relations have heretofore subsisted between the professors at Cork and the students, and the latter have displayed exemplary conduct and bearing. It is pleasing, therefore, to say that the missile-throwing was confined to the comparatively few of the great number of students present. Several degrees in arts and other faculties were conferred by the President, Dr. B. C. A. Windle, as Pro-Vice-Chancellor of the University. The degrees of M.B., B.Ch., B.A.O. were conferred on three students of the College. One of the three obtained first-class honours and another second-class honours. Dr. John Joseph Kearney, medical officer of the Rosscarbery Dispensary district, a former distinguished student of the Cork College, got his M.B. and B.Ch. degrees at the Royal University three years ago. Last spring the National University conferred on him the degree of M.D. with first-class honours, and on the strong recommendation of the Board of Examiners owing to the excellence of his answering awarded him a gold medal. On this occasion the Diploma of Public Health was conferred on him, Dr. Kearney having won first-class honours.

Nov. 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Sciatica.

AT a meeting of the Société Médicale des Hôpitaux held on Oct. 14th M. Ramond, M. Deffins, and M. Pinchon said that in the treatment of 65 cases of primary sciatica they used one or other of the following methods: injection of artificial serum or solution of a magnesian salt in the vicinity of the nerve, epidural injection of cocaine, injection of air filtered through cotton wool, and *siphonage*. These were, in their opinion, the most active measures available for the purpose. The injection of air often gave excellent results in comparison with the effects produced by the other injections, and on account of its simplicity it deserved a good place on the list of therapeutic procedures. It was impossible to say which was the best form of treatment, because a case of sciatica which derived no benefit from injections in the vicinity of the nerve might improve or might even disappear entirely after injections of sterilised air or the epidural injections already mentioned. In the treatment of obstinate sciatica it was therefore advisable to make successive trials of these various methods.

Bullet Wounds of the Spleen.

Several cases of wounds of the spleen inflicted by revolver bullets were recently communicated to the Surgical Society by M. Guibé, who in operating on the patients was guided not by the signs of hæmorrhage but by the contraction of the abdominal wall. M. Auvray, who had been requested to submit a report on these cases, said that he had found 95 recorded instances of wounds of the spleen. The principal point of interest was the choice of the operation to be performed. When the wounds had been inflicted with a knife the majority of the operators considered that the transdiaphragmatic route was the best, leading as it did directly to the convex surface of the spleen. The circumstances were by no means the same for bullet wounds of the spleen, because these might be accompanied by serious lesions in distant parts of the abdomen, and for such wounds the operation recommended was laparotomy, either median, lateral, or transverse, always keeping in mind the possibility of thoracotomy being afterwards necessary. M. Auvray, however, considered that a surgeon ought to be very cautious in undertaking extensive secondary operations on the thorax because they rendered the prognosis less favourable. Splenectomy was generally performed, but under certain conditions it was better to attempt preservation of the viscus with suturing. The mortality was very high—55 deaths among the 95 recorded cases. The facts observed by M. Guibé raised the question of producing artificial pneumothorax, an operation which most surgeons considered to be not very serious. Wounds in the diaphragm ought always to be sutured, for if this was omitted secondary hernia would occur; the experiments of M. Ripetto had clearly shown that such sutures held well, and that a cicatrix was formed.

Fatal Accident to Dr. Armand Trousseau.

Dr. Armand Trousseau, grandson of the celebrated professor of clinical medicine, has recently lost his life in a motor-car accident. Through the overturning of the vehicle which he was driving his skull was fractured and he was killed on the spot. Having been admitted *interne* in 1878, he soon applied himself to ophthalmic work. Eventually he became medical attendant to the blind asylum known as Quinze-Vingts, and was subsequently selected as director of the Rothschild institutions for the blind.

Sleeping Sickness.

At the October meeting of the Société de Pathologie Exotique two communications on the subject of sleeping sickness were read. The first was by M. Martin and M. Ringelbach on the preventive measures against the disease undertaken at Brazzaville and in the Congo district in 1909. Patients infected with trypanosoma received treatment at the Pasteur Institute in Brazzaville. A system of inspection in connexion with the disease was established, natives who travelled from place to place had to obtain sanitary passports, and none were employed on military service or as porters until they had been specially examined. In the second communication M. and Mme. Yakimoff recorded their observations on the action of Ehrlich's new remedy "606" on 14 rats infected with Trypanosoma gambiense. From 1 to 14 days after the appearance of trypanosomata in their blood they received injections of 0·15 gramme of "606" per kilogramme of the animal's weight, after which they were kept under observation for periods varying from 49 to 80 days. The parasites disappeared from the blood in from 45 to 62 minutes after the injections. Animals which received simultaneous injections of "606" and trypanosoma virus did not become infected.

Nov. 7th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Jubilee of the Berlin Medical Society.

THE Berlin Medical Society celebrated its fiftieth anniversary by a special meeting on Oct. 26th. Professor Senator, the President, gave a short history of the society, which was formed by the amalgamation of two associations designated respectively the Society for Scientific Medicine and the Society of Berlin Medical Men. During the early years of the new society it received communications on miscellaneous

professional questions, as well as on subjects connected with medical science, but in course of time it confined itself to scientific subjects, the professional matters being left to other newly-formed associations of practitioners. Many important discoveries were first made public by papers read before the Berlin Medical Society; it is also the largest medical society in Germany, the number of members being about 1600. The rector of the University, Professor Rubner, the dean of the Medical Faculty, Professor Ziehen, and representatives of other medical societies then delivered short congratulatory speeches on the jubilee occasion. Professor Orth, Vice-President, announced that the society had admitted a number of prominent medical men in Germany and abroad to the honorary membership, and that Professor Senator had been made honorary President. The honorary members included Dr. Boas and Dr. Kessler, the only survivors of the original founders of the society, the other German honorary members being Professor Waldeyer, Professor Naunyn, Professor Röntgen, and the chief of the Army Medical Corps, Dr. von Schjerning. The foreign honorary members included Professor Exner and Professor Fuchs of Vienna, Lord Lister, Professor Laveran of Paris, Professor Lépine of Lyons, Professor Golgi of Rome, Professor Murri of Bologna, Professor Jacoby of New York, Professor Keen of Philadelphia, Professor Armauer Hansen of Christiania, Professor Retzius of Stockholm, Professor Korany of Budapest, Professor Pawlow of St. Petersburg, Professor Ramon y Cajal of Madrid, Professor Salomonsen of Copenhagen, and Professor Kitasato of Tokio. Professor Landau, Vice-President, made a statement relative to the Virchow Haus, the future home of the society, and announced that Professor Virchow's widow had bequeathed to the society his valuable collection of specimens which were to be placed in the new premises and would form a Virchow Museum. In the evening the members of the society and their guests were entertained at a "Commers" in the Philharmonic.

Rabies in Germany.

406 persons have been officially recorded as having been bitten by rabid animals in Prussia during the year 1909. Of these patients 68·2 per cent. were men and 31·8 per cent. were women. The majority of the cases happened in the districts adjoining the Russian frontier, whilst no case at all happened in the provinces of Westphalia, Hanover, and Saxony. The animals inflicting the injuries are described as 190 dogs, 5 cats, 3 horses, and 4 other domesticated animals. In 19 cases the patient contracted the disease from other persons. Of the total number of persons bitten 374 (92·1 per cent.) received Pasteur treatment—203 in the Institution for Infectious Diseases in Berlin and 171 in the Hygienic Institute at Breslau. There were 10 deaths in all, 8 of the deceased having been treated by Pasteur's method, so that among 374 persons treated in this way 8 (2·13 per cent.) died, and among 32 persons not treated in this way 2 (6·25 per cent.) died.

A New Dietetic Preparation.

Professor von Noorden of Vienna, writing to the *Berliner Klinische Wochenschrift*, has given a very favourable description of a new dietetic preparation termed "riba," consisting almost entirely of albumins and albumose with only a small quantity of extractives such as purin bodies and kreatinin. When mixed with three parts of water it has a brown colour, a smell of glue, and a rather bitter taste, which disappears after the preparation has been added to some ordinary article of food having a more or less fluid consistence. Clinical observations showed that from 60 to 100 grammes could be administered daily without causing digestive troubles, although many of the patients suffered from diseases of the stomach, constipation, chlorotic dyspepsia, and similar conditions. That the preparation was very readily absorbed was proved by the fact that the elimination of nitrogen in the fæces was only very little increased by the administration of the substance. One of the experiments made for this purpose was as follows. A patient was given a nutritive enema consisting of 300 grammes of a "riba" solution containing 14·5 grammes of nitrogen. Three hours later the rectum was washed out, with the result that only 1·85 grammes of nitrogen was present in the fluid, so that 12·65 grammes had been absorbed within three hours. "Riba" should not be given in milk or bouillon because of its bitter taste which disappears when it is mixed with thick soup, such as a purée of potatoes or carrots, or with gruel made with oatmeal or barley. The indications for the use of "riba" are the same as for other albuminous preparations. In the uric diathesis it is as harmless as vegetable albumin because it contains only a very small quantity of purin bodies.

Oct. 31st.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Insanitary State of Southern Italy.

THE speech of the Minister of the Interior, Signor Calissano, at Alba last week has made a very favourable impression on medical circles in Italy, showing as it does an unusual interest in and grasp of sanitary problems on the part of an Italian politician. The greater part of Signor Calissano's discourse was devoted to those sanitary questions which are indeed of outstanding importance for Italy at the present moment and especially for the southern portion of the peninsula, and which have been raised by the recent outbreak of cholera and by the scarcity and even total lack in many places of a sufficient supply of potable water. In regard to cholera, after a brief reference to its steady advance during the last five years through central and eastern Europe and to the geographical position of Italy, interposed like a long barrier between Europe and the East, and in consequence peculiarly exposed to the danger of invasion by Asiatic diseases, the Minister discussed the origin of the outbreak in Italy, pointing out the difficulty or rather the impossibility of ascertaining the precise mode of its entrance, not only on account of the well-known fact that the germ may be carried by persons apparently in good health, but also because of the grave error committed by certain medical men of Bari, under whose observation the first cases came, in failing to recognise the disease as cholera. Before this blunder was detected by Professor Gosio, the able chief of the bacteriological laboratory of Rome, who was sent expressly to investigate the so-called gastro-enteritis on the spot, many cases had already occurred, and it was no longer practicable to trace their original source. The nature of the disease once definitely recognised, the action of the sanitary authorities was prompt and effective both in dealing with the epidemic at the various points at which it had appeared and in adopting protective measures against its possible outbreak at any other centre throughout the kingdom. The result has been eminently satisfactory, for if not yet entirely extinguished the epidemic in the course of a few weeks has all but died out, only a few sporadic cases occurring here and there, which in their turn are promptly isolated so as to prevent effectually any further spread of the malady. This happy result has been achieved in the face of the greatest difficulties, caused both by the attitude towards repressive measures taken up by the ignorant and superstitious peasantry and by the fearfully insanitary conditions in which these poor people exist. In the Puglie the population, composed chiefly of peasants, live either in dwellings underground or shut up in hovels without air or light, huddled together in crowds in a state of indescribable misery and abandonment, their water-supply drawn from wells contaminated with every filth, and all of them poverty stricken, with no resources to fall back upon in such a crisis, and unable to obtain work because those who might employ them are likewise themselves destitute. The local communes, at the end of their resources and lacking the means of carrying out the necessary sanitary measures, are quite unable to cope with the situation, and, worst of all, the public spirit in many places is so demoralised that it gives way to panic, the terror-stricken people taking to flight, concealing the suspected cases and deaths, and reviving all the old mediæval traditions of poisoning and wilful spread of the disease by the doctors. In these circumstances it is not surprising that riots, and even loss of life, have in some instances been the outcome of attempts by the sanitary authorities to enforce isolation of the infected and of suspected cases. But by the exercise of courage, tact, and patience these difficulties have been nearly always peacefully overcome, a fact which reflects the highest credit upon the officials to whom these trying duties have been entrusted, and their final victory

seems now well in sight. Signor Calissano contrasts the present epidemic, in which the number of victims has not amounted to more than 1000, with that of 1893, when there were over 3000; that of 1887, when there were over 8000; and that of 1884–86, when the grand total was well over 50,000, and thinks that considering the duration of the outbreak, the wide extent of country affected, and the invasion of towns and cities where the contagion might easily have spread, there is reason to be proud of the victory which has been already gained. At the same time, he deprecates any relaxation of the precautions now being taken, bearing in mind the possibility of a recrudescence of the disease in the spring and the enormous loss such an outbreak would inflict on the whole country, more particularly by compromising the success of the great patriotic celebrations at Turin and Rome in 1911, and of the two exhibitions of industry and art to be held in these cities and in which the whole world is taking part. As a result of the visit paid by Ministers to Naples and the other infected districts of the south in connexion with the epidemic, the Government have realised the necessity of a great reform in the organisation of the sanitary services, including the institution of courses of lectures on the theory and practice of epidemiology, with special attention to exotic diseases and to the technique of disinfection; of schools for nurses of both sexes; and of a different system in the creation of local sanitary offices, or at least of a more rigorous method in the selection of the local sanitary officials. A project of law has also been prepared providing for the filling up of the attenuated ranks of the present sanitary *personnel* and for the supply of more adequate means for the hygienic defence of the country. Turning to the question of the water-supply, Signor Calissano announced that the Government were preparing, or had already prepared, various projects dealing with the problem, and especially one of a general kind enacting that all communes, even to their smallest subdivisions, shall be provided with potable water. He explained how under the present wholly inadequate system there are 17 millions of the inhabitants still without such a supply, and said that the Government are determined, by facilitating the purchase of pure sources and by the construction of aqueducts, to make good this deficiency, so that everyone, with the exception only of those living scattered in remote country districts where the expense would be prohibitive, may be able to obtain pure drinking water. For this purpose it will be necessary to raise funds by special imposts which will be termed hygienic taxes. Since the above speech was delivered the epidemic of cholera has meanwhile greatly diminished, Naples in particular, where its spread was most dreaded, having now had no cases for several days. The measures taken in Rome for dealing with the few imported cases which were promptly isolated there have been entirely successful, no instance having occurred of a spread of the infection from any of them.

Nov. 5th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the New Rockefeller Hospital.

THE opening on Oct. 16th of the new Rockefeller Hospital was attended by some 2000 persons, among whom were to be noticed many of the most internationally known of America's physicians. This hospital differs from all others in that while it will at all times be a special hospital, devoting itself entirely to the care and investigation of certain diseases and opening its doors to subjects of those diseases alone, this specialisation will not be permanently in one direction but will be subject to change at the discretion of the Board of Scientific Directors, in accordance with the variations in the nature of the problems that from time to time most urgently call for solution. Three or four diseases are to be selected for study and only subjects of these diseases will be received to benefit by the care of the institute and hospital, which will be given gratuitously to the full extent of its capacity. All the most modern resources that the ingenuity of scientific man can devise will be brought to the aid of both patient and science. At the same time, each one of those in attendance will be not only artist but scientist. While exercising the highest that is humanly attainable at the time in the direction of cure, they will devote their entire time and energies, already trained in research, to solving the problems which yet remain in the particular diseases for the time being under investigation. No private practice, not even the diffusion of interest that inevitably takes place in a general hospital, will be there to weaken the concentration of concerted observation from different viewpoints on the one subject in all its bearings. The investigation into the particular disease will go on simultaneously and coöperatively by both laboratory and clinical methods of research. Here, for the first time in its history, medical scientific research will be unified and complete, with no further ground for impeachment by the laboratory man of the inaccuracy and inexactness of the clinician's method or counter assertions by the clinician that the laboratory man forgets that he is dealing with a living person, not with a test-tube. Here the laboratory and the clinic will work side by side under the care of men each equally familiar with the working of both methods and specialising their duties, if at all, merely for convenience, not from necessity. The evolution of the Rockefeller Institute exemplifies probably the sanest conception of the way progress in medicine lies that the world has ever seen. Mr. Rockefeller took counsel with medical scientists of the first rank in whom he had full confidence as to what problems in medicine most immediately called for solution, and having convinced himself of the soundness of their views gave them the sum of $200,000—this was in 1901—to deal with and carefully watched what use they made of it. Being satisfied with the practical utility of their results, in 1902 he gave a further sum of $1,000,000 to provide the necessary buildings and equipment for the more centralised and controllable continuance of the work, and to bear the running expenses for a few years. This gift was further amplified in 1907 by the munificent endowment of $2,600,000 for the institute. In the meantime it had been demonstrated to Mr. Rockefeller's keen sagacity that a hospital to afford unfettered means for appraising clinically the results arrived at by laboratory methods was essential, if those results were to be fairly tested by competent men familiar with their method of working. The hospital thus initiated was opened on Oct. 16th, and at the same time Mr. Rockefeller added a further endowment fund of $3,820,000. The entire estate and income of the institute, including the new hospital, was on that day formally taken possession of by a board of trustees, consisting of John D. Rockefeller, jun., Frederick T. Gates, William H. Welch, Starr J. Murphy, and Simon Flexner, thus converting the institute from a private concern to a public trust. To quote from the statement issued by the trustees, they "hold the entire income at the disposal and under the full control of the Board of Scientific Directors, which is constituted as follows: Dr. William H. Welch, of Baltimore, president; Dr. T. Mitchell Prudden, of New York, Dr. L. Emmett Holt, of New York, secretary and treasurer; Dr. Christian A. Herter, of New York, Dr. Simon Flexner, of New York, director of laboratories; Dr. Herman M. Biggs, of New York, and Dr. Theobald Smith, of Boston." It would be impossible to conceive of a stronger or more workable board. The medical staff consists of Dr. Rufus L. Cole, director; Dr. Christian A. Herter, physician to the hospital; Dr. G. C. Robinson, resident physician; and Dr. Draper, Dr. Marks, Dr. Swift, and Dr. Peabody, internes, each one of whom has had special training in investigation work. The hospital is neither a separate institution nor an addendum to the Rockefeller Institute; it forms an integral part of the institute itself, with the laboratory of which it is in actual contiguity, being connected with it by the isolation building, a two-storey structure consisting of a series of rooms separated from one another only by glass partitions, thus forming a thoroughly germ-proof series, yet capable of control by a single night nurse. The ventilation is specially provided for by a straight copper tube from each room carried through the roof, and fitted at the bottom with an aspirating coil and an ejector, so that the cleansing with live steam is a simple matter in the hands of the attendant. To describe the laboratories, workrooms, living rooms, patients' rooms, dressing rooms, operating rooms, kitchens, offices, &c., would take up too much space. Suffice it to say that the crowd of competent critics who thronged to the opening seemed to be agreed that the hospital represents the highest effectiveness

at present attainable, from the view-point alike of patient, physician, and investigator. The hospital was opened for the reception of 70 patients on Oct. 20th. The diseases first selected for special study are infantile paralysis, because of its appearance in epidemic and malignant form, and pneumonia and heart diseases, which according to recent statistics show the most marked increase in the death-rate.

Alvarenga Prize of the College of Physicians of Philadelphia.

The Alvarenga prize of the College of Physicians of Philadelphia for 1910 has been awarded to Dr. M. Katzenstein of Berlin, Germany, for an essay entitled "The Formation of an Arterial Collateral Circulation in the Kidney." The College announces that the next award of the prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $180, will be made on July 14th, 1911, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and must be received by the secretary of the college on or before May 1st, 1911. They must be sent without signature, marked with a motto and accompanied by a sealed envelope having on its outside the motto and within the name and address of the author.

Nov. 1st.

Medical News.

UNIVERSITY OF BRISTOL.—At the first congregation for the conferring of degrees the following graduates of the Faculty of Medicine were admitted. It will be noticed that many of these were past students of University College, Bristol, who had already graduated in another University, and were admitted to the "ad eundem" degree:

Bachelor in Medicine and Bachelor in Surgery.—William Marmaduke Bergin, M.B., B.S. Lond., Charles William James Brasher, Arthur Lancelot Flemming, William Wilfrid King, Leonard Augustus Moore, Leonard Newsom Morris, Frederick Charles Nichols, Thomasina Georgina Prosser, M.B., B.S. Durh., William Stuart Vernon Stock, M.B., B.S. Lond., John William Taylor, and Andrew John Metford Wright, M.B., B.S. Lond.

Bachelor in Medicine.—Philip Graham Stock, M.R.C.S., L.R.C.P., D.P.H., and Vivian Bartley Green-Armytage (*in absentiâ*).

Master of Surgery.—Clifford Arthur Moore, M.S. Lond.

Doctor of Medicine.—Henry Devine, M.D. Lond., Arthur Hill Joseph, M.D. Lond., and William Barrett Roue, M.D. Durh.

Doctor of Medicine and Bachelor of Surgery.—Professor Walter Carless Swayne, M.D., B.S. Lond.

Honorary Degree of Doctor of Science.—Professor Conwy Lloyd Morgan, LL.D. (*honoris causâ*), Aberdeen, F.R.S.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Giovanni Razzaboni has been recognised as *privat-docent* of External Pathology.—*Bonn:* Dr. Otto Dragendorff has been recognised as *privat docent* of Anatomy, and Dr. Wassermeyer of Kiel as *privat docent* of Psychiatry.—*Buffalo:* Dr. Francis C. Goldsborough of Baltimore has been appointed to the chair of Midwifery in succession to Dr. Matthew D Mann resigned.—*Cagliari:* Dr. Efisio Orrù has been recognised as *privat docent* of Anatomy.—*Florence:* Dr. Ettore Levi has been recognised as *privat-docent* of Neurology.—*Greifswald:* Dr. F. A. König of Altona has been appointed Professor of Clinical Surgery in succession to Dr. E. Payr.—*Halle:* Dr. Ernst Laqueur of Königsberg has been recognised as *privat-docent* of Physiology, and Dr. Josef Igersheimer as *privat-docent* of Ophthalmology.—*Kharkoff:* Dr. B. G. Priêvalski has been appointed Professor of Operative Medicine and Topographic Anatomy.—*Marburg:* Dr. Wenckebach of Groningen has been invited to succeed Professor Braner, and Dr. Wilhelm Zangemeister has been offered the chair of Midwifery, with charge of the Female Clinic, in succession to Dr. Stoeckel, who goes to Kiel.—*Munich:* Dr E. Edens has been recognised as *privat-docent* of Medicine.—*Naples:* Dr. M. De Vico has been recognised as *privat-docent* of Medical Diagnosis, and Dr. V. Marcopi as *privat-docent* of External Pathology.—*Parma:* Dr. Carlo Ferrai, Professor in Modena, has been appointed to the chair of Forensic Medicine.—*Pavia:* Dr. U. Carpi and Dr. E. Morelli have been recognised as *privat-docenten* of Medical Pathology, Dr. R. Pandolfini as *privat-docent* of Surgical Pathology, and Dr. G. Ciuffo as *privat-docent* of Dermatology.—*Prague (German University):* Dr. Hans Rotky has been recognised as *privat-docent* of Medicine, and Dr. Robert Salus as *privat-docent* of the Special Pathology and Therapeutics of the Eye.—*Turin:* Dr. L. Borelli and Dr. P. F. Tuccòla have been recognised as *privat-docenten* of Medical Pathology, Dr. I. Valobra as *privat-docent* of Neurology, Dr. Giacinto Mosso as *privat-docent* of Ophthalmology, and Dr. A. Nieddu as *privat-docent* of Otology and Laryngology.—*Warsaw:* Dr. G. P. Sakharoff of Kazan has been appointed Professor of Medical Chemistry.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, Sir James Crichton-Browne, Treasurer and Vice-President, in the chair, when Professor H. S. Hele-Shaw, F.R.S., Dr. A. Latham, and Dr. StClair Thomson were elected members among others.

THE LE TOUQUET GOLFING TOURNAMENT FOR THE PROFESSIONS.—The Le Touquet Golfing Tournament for the Professions of the Church, Navy, Army, Medicine, Law, and so on, will be held at Le Touquet, near Boulogne, during the week-end Dec. 10th to 12th, 1910. Play will be as follows: 18 holes Match Play *v.* Bogey, under handicap. Class I., handicaps 12 and under. Class II., handicaps over 12. Players can take out as many cards as they wish. Prizes will be given by the Le Touquet Golf Club. Intending competitors should send names and addresses as soon as possible to L. Eliot Creasy, M.R.C.S., L.R.C.P., 36, Weymouth-street, London, W., when information concerning vouchers for cheap week-end tickets will be forwarded.

ASSOCIATION OF PUBLIC VACCINATORS OF ENGLAND AND WALES.—The annual meeting of this association was held at the Hotel Cecil, London, on Oct. 28th. Mr. J. C. Bradshaw (Liverpool), the President, occupied the chair. The minutes of the last annual meeting were read and confirmed. A long discussion followed relating to the general business and financial affairs of the association. A proposition was carried with enthusiasm electing Dr. A. E. Cope (London) to be President for the ensuing year. The retiring council, with an addition in the place of one resignation, were re-elected. In the evening the annual dinner was held at the Hotel Cecil. Among the guests were Dr. A. P. Hillier, M.P., Dr. R. A. Farrar (Medical Inspector, Local Government Board), Mr. W. B. Parsons (THE LANCET), and Mr. G. S. Elliston (*Medical Officer*). Dr. Hillier, in responding to the toast of "The Guests," which was proposed in a humorous speech by Mr. J. Foster Palmer (London), expressed great pleasure at meeting so many of his professional brethren who were engaged in carrying out that branch of practice which dealt with the application of preventive medicine. When a future historian came to deal with our age he believed it would be recorded that nothing more markedly distinguished the period than the wonderful work which began with Jenner and which had been carried on by Pasteur, Lister, and Koch to such an extent as to have conferred upon mankind at large probably a greater aggregate of good results than the world has ever seen. As that splendid work expanded they still had sceptics to deal with. They might, however, console themselves that people were still living who believed the world to be flat and that mankind had benefited nothing from experiments performed upon lower animals. These people might be placed in the same category as those who believed vaccination was worthless. When he was out in South Africa he had the opportunity of witnessing the effects of an epidemic of small-pox on an unvaccinated community. Many real conscientious objectors existed there among the people, who, being Mahommedan by faith, had as an article of their belief the notion that it was an insult to the Deity to withstand disease. Before the epidemic was over many of these came to be vaccinated as a result of their observations among the vaccinated. Their objections might have been excusable, but for the life of him he could never understand how the conscience of the objector in this country could enter into the question. Vaccination had been since that time carried out in South Africa with excellent results. The evidence regarding the protective value of vaccination was so overwhelming that he could not understand how any sensible man could question its efficacy. He believed that small-pox could never be successfully combated by simply vaccinating the contacts. If the bulk of the profession were of that opinion he suggested the time had come when the leading men of the profession should meet to

make a public protest. Nothing would carry more weight with the House of Commons than an opinion judiciously expressed by the leaders of the profession. Other toasts included "The Association of Public Vaccinators of England and Wales," proposed by the President (Dr. Cope) and responded to by Mr. Bradshaw, and "Public Health and Poor-law," proposed by Dr. A. Drury (Halifax), and responded to by Sir H. W. Newton (Newcastle-on-Tyne).

ROYAL SOCIETY OF ARTS.—The programme for the 157th session of the Royal Society of Arts is being issued to the members. The following papers are among those announced: Sir Henry H. Cunynghame, K.C.B., Detecting Fire-damp; Dr. Vaughan Cornish, the Panama Canal; Mr. A. Montgomery, Mining in Western Australia. On the four Mondays before Christmas Mr. C. R. Darling is to give a course of Cantor lectures on Industrial Pyrometry. There is a full list of papers and lectures for the part of the session after Christmas.

SOUTHWARK SLUM CLEARANCE SCHEME.—The London County Council on Nov. 8th decided, on representations by the medical officers of health of Southwark and Bermondsey, to spend £387,000 on a clearance scheme in the Tabard-street area, off the Borough High-street, and two smaller slums in the vicinity. It is proposed to re-house half the displaced population in block dwellings, to lay out five acres of the Tabard-street area as an open space, and to use the remaining three acres of the site for commercial purposes. The Housing of the Working Classes Committee stated that the area was so badly planned and the houses in such a deplorable state that only a complete clearance would be of any use. The following particulars with regard to the death-rate are significant:—Deaths from all causes, 1904–08: Tabard-street area, 36 8 per 1000; Southwark, 18 2; and London generally, 14 9. Phthisis death rate: Tabard-street, 3·83; Southwark, 2·09; and London, 1·44. The principal endemic diseases: Tabard-street, 6·07; Southwark, 2·29; and London, 1·71.

THE FEEDING OF NURSES.—Under the auspices of the National Food Reform Association a conference of hospital matrons was held in Caxton Hall, London, on Nov. 5th, to discuss the question of nurses' food in hospitals and similar institutions. Miss Rosalind Paget presided, and among the speakers were Miss Musson, matron of the Birmingham General Hospital, Miss Cox Davies, matron of the Royal Free Hospital, and Miss Barton, matron of the Chelsea Infirmary. The general complaint, as expressed by many representatives, seemed to be the monotony of hospital fare, and many suggestions were made as to the practicability of altering this by adopting some of the French *réchauffé* dishes, and the German methods of cooking vegetables. The chief difficulties apparently lay in the extra thought in planning which would be thrown upon the caterer and upon the intelligence of the cook. But all were agreed that if the result is to be greater vigour of mind and body in the nurses, who are, after all, responsible for carrying out the medical treatment of the patients, then it is certainly worth while attempting to overcome these difficulties. One speaker said she thought the food was not of so much importance as the time taken for meals. In many institutions the nurses have only half an hour for dinner, out of which at least five minutes is taken up in going to and from the wards and dining-room.

THE LONDON COUNTY COUNCIL AND THE DEPARTMENTAL COMMITTEE ON CORONERS.—The General Purposes Committee submitted to the London County Council on Nov. 8th a long report in which were set forth the points of divergence between the recommendations of the Departmental Committee on Coroners and the resolutions in which, from time to time, the Council has expressed its views as to desirable amendments in the law. The General Purposes Committee thought that, subject to certain modifications, Sir William Collins's Coroners' Law and Death Certification (Amendment) Bill would be acceptable to the Council, and that the Government should be urged to give facilities for its passage during the autumn session. The Council, however, would do well to re-affirm its views on those points on which the Departmental Committee came to a different conclusion. These were that coroners should be paid by salary and be required to devote their whole time to the duties; the number of jurymen should be not less than six nor more than 11, and should be summoned strictly by rota; the view of the body by the jury should be dispensed with, except in cases in which the coroner and a majority of the jury thought it necessary; and that no fees for giving evidence or making post-mortem examinations should be paid to medical officers employed in rate-aided institutions.

DONATIONS AND BEQUESTS.—Prince Alexander of Teck has now received nearly £5000 for the Prince Francis of Teck Memorial Fund in aid of the Middlesex Hospital. This sum includes donations of 100 guineas from the King and the Queen, and a magnificent gift of £1000 from Mr. J. Bland-Sutton.—An anonymous gift of £1000 has been made towards the erection of new buildings for the Nottingham and Midland Eye Infirmary.—An anonymous gift of £5000 has been made to the governors of the Victoria Infirmary, Glasgow, for the purpose of building and equipping a clinical research laboratory.—The Manchester Royal Infirmary has received from Mrs. J. E. Platt a cheque for £1000 for the purpose of endowing a bed in that institution in memory of her late husband, who for many years was an honorary surgeon to the Royal Infirmary.

ASSOCIATION OF CERTIFYING FACTORY SURGEONS PRESENTATION TO THE LATE HONORARY SECRETARY.—The annual dinner of the Incorporated Association of Certifying Factory Surgeons was held at the Queen's Hotel, Manchester on Nov. 4th. Mr. W. F. Dearden of Manchester, who has been honorary secretary of the association for the last 11 years, was elected President, and took the chair at the function, which was well attended by members from all parts of the country. After "The King" had been duly given and responded to, Mr. A. A. Haworth, M.P., responding to the toast of "The Houses of Parliament," proposed by Dr. J. Brassey Brierley, said that Parliament could not legislate one inch in front of public opinion. The experience of the past fully supported this view. In their efforts they must carry the people with them. The factory legislation of the past and the legislation now proposed, which would be passed into law, would be looked upon in times to come as one of the factors in the great march of civilisation and progress. Mr. T. Fort then made a presentation to Mr. Dearden on behalf of the association. It consisted of a silver tray, tea service, entrée dishes, and a gold bracelet for Mrs. Dearden. Mr. Fort spoke of the work of Mr. Dearden in promoting health in the factory and among school children, remarking that he was one of the leading authorities on industrial disease, and had contributed valuable papers to various medical and scientific associations at home and abroad. Mr. Dearden had also been one of the prime movers in securing the charter of incorporation. Mr. Dearden, in responding, said that their greatest triumph had been achieved when they succeeded in securing the retention of the old statutory obligation requiring the investigation into the causation of so-called preventable factory accidents by the certifying surgeon, and this was principally owing to the way in which every individual member used his efforts to convert any Member of Parliament with whom he happened to be acquainted. The British Medical Association and Sir Victor Horsley were also entitled to a share of the credit. The modern and only successful method by which a body of men engaged in the same calling could hope to improve their common condition was by association, and he had striven hard to convince certifying surgeons of this principle, which stood for uniformity of views and uniformity of action. The departmental returns for 1900, at the beginning of which year he took office, showed that 1882 certificates had been refused for physical incapacity; each year these figures had gradually improved until at the end of 1909 they had gone up to 7738. The association had convinced the authorities of the tremendous advantage to juvenile labour of legalising the regulation of the nature of employment to the physical capacity of the applicant by authorising the certifying surgeon to affix conditions to his certificate, and it was members of the association who were responsible for the 5775 conditional certificates granted last year. He concluded by speaking in terms of great praise of the work of Dr. T. M. Legge and Dr. E. L. Collis, the medical inspectors of factories attached to the Home Office. Sir William Bailey proposed the "Factory Department of the Home Office," and Professor G. R. Murray, in responding for

"The Visitors," made the suggestion that any wealthy employer who wished to devote a sum of money to a really good object could not do better than endow a research scholarship for the study of industrial disease.

Colonel Sir David Bruce's name should have been included in the list published last week of those who have joined the Organising Committee of the Seventeenth International Congress of Medicine.

Mr. Ernest Hook Buckell, who on Nov. 1st was elected for the first time a member of the Chichester city council, has been placed on the Commission of the Peace for the city.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the annual meeting of Fellows and Members of the Royal College of Surgeons of England, which is to be held at the College on Thursday next, Nov. 17th, the President will place before the meeting the report of the Council for the collegiate year ending August 1st, 1910. Mr. Joseph Smith, J.P., M.R.C.S., is to propose the following motion:—"That this twenty-sixth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council, which, as now constituted, does not represent the whole corporation, and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation." The President takes the chair at 3 o'clock.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London.
Practical Physiology. Edited by M. S. Pembrey. Contributors:—A. P. Beddard, M.A., M.D., J. S. Edkins, M.A., M.B., Martin Flack, M.A., M.D., Leonard Hill, M.B., F.R.S., J. J. R. Macleod, M.B., M. S. Pembrey, M.A., M.D. Price 14s. net.

BIRTHS.

BURGESS.—On Nov. 2nd, in London, the wife of J. Hay Burgess, M.B., F.R.C.S., Capt., I.M.S., of a daughter.

HUMPHRY.—On Nov. 1st, at St. John's-street, Chichester, the wife of Philip R. Humphry, M.R.C.S., L.R.C.P., of a son.

ROBERTS.—On Nov. 5th, at Kalimpong, Bengal, the wife of C. L. Digby Roberts, M.B., Ch.B. Edin., Church of Scotland Mission, of a daughter. (By cable.)

WEBB JONES.—On Oct. 21st, at Henrietta House, London, the wife of A. Webb Jones, F.R.C.S., of a son.

WILSON.—At College-crescent, Fitzjohn's-avenue, N.W., the wife of J. Clark Wilson, M.D., M.R.C.P., of a daughter.

WOOD.—On Oct. 31st, at Wrington, Somerset, the wife of W. Vincent Wood, M.R.C.S., L.R.C.P., of a daughter.

DEATHS.

BINGHAM.—On Nov. 2nd, at Derby, John Joseph Bingham, M.D., of Alfreton, Derbyshire, aged 66 years.

CLARK.—On Nov. 4th, at Cross Deep, Twickenham, William Thomas Marston Clark, M.R.C.S., L.R.C.P., D.P.H., aged 53 years.

HOLMESTED.—On Nov. 5th, 1910, at Tuxford, Notts, Charles Wakeham Holmested, L.R.C.P., L.R.C.S., aged 63 years.

LORD.—On Nov. 5th, at Woodfield-avenue, Ealing, Richard Lord, M.D., M.R.C.S., in his 73rd year.

IN MEMORIAM.

IN memory of Henry Hugh Clutton, M.C. Cantab., F.R.C.S., of 2, Portland-place, who passed away Nov. 9th, 1909, aged 59.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HATTERS' "NEW DISEASE."

A CASE of importance to the hatting industry came before Judge Brown, K.C., at the Hyde county court last month, and the decision of the judge was reserved till recently, the questions at issue not being quite easy. The applicant was a working hatter and sought compensation for mercurial poisoning. The theory is that the mercury got into the system by being inhaled from the fur impregnated with it. The mercury was probably used in the form of corrosive sublimate for the preservation of the skins. In his judgment his honour doubted whether a workman could be said to be employed in a process, &c., when the employer did not provide the mercury or even know it was there. His honour thought not, and said "it would open a very wide door if it were otherwise, and would establish liability wherever an employer used in his business any article procured elsewhere by him, which wholly or in part was made of, or contained, or was even impregnated with lead, mercury, phosphorus, or arsenic." The judge was of opinion that Schedule III. of the Workmen's Compensation Act only referred to a process in which the employer himself used the mercury in the ordinary acceptation of the term, and therefore that this case was not within the Act. He dismissed the application with costs and invited an appeal. If this is the law, the judge had no choice as to what his decision must be. But it tells heavily against the workers, and to the non-legal mind it does not seem equitable that they should be exposed to such risks without a chance of compensation. The obvious thing would be, as it seems, to get rid of the poisonous impregnation to prevent the danger to health and life, against which at present there appears to be no protection.

LEICESTER MEDICAL UNION AND THE PEARL LIFE ASSURANCE COMPANY.

To the Editor of THE LANCET.

SIR,—I have been requested to forward you the following resolution, passed unanimously at the last meeting of members, which it is hoped you will insert in your journal:—

[RESOLUTION.]

"That the members of the Leicester Medical Union strongly disapprove of the new scale of fees proposed by the Pearl Life Assurance."

I am, Sir, yours faithfully,

Leicester, Nov. 7th, 1910. DOUGLAS BRYAN.

WANTED, A SUGGESTION FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—In reply to "M.D.'s" appeal in THE LANCET of Nov. 5th, p. 1392, may I venture to suggest to him that, if he is free from any cause which may set up reflex irritation, such as enlarged prostate, renal or cystic calculus, &c., he would obtain relief from his enlarged knee-joints by applying two blisters, each 4 × 2, one on each side of the last dorsal vertebra. He will find full directions regarding this mode of treatment on p. 929 of THE LANCET of Sept. 24th last, where he will also find the reasons for adopting it.

I am, Sir, yours faithfully,

Nov. 8th, 1910. P. W. L.

OLD MEDICAL BOOKS.

AMONG a three days' sale of books at Sotheby's recently were included a few lots of medical interest. A black letter by Ulric von Hutten, "Of the wood called Guaiacum that healeth the Frenche Pockes, and also helpeth the Goute in the feete, the Stone, Palsey, lepre, dropsy, fallynge evil, and other diseases, translated into Englyshe by Thomas Paynall," small 4to, 1540, was sold for £8 15*s*. Another black letter, a fine copy, of Nicholas Monardus' "Joyful Newes out of the New-found Worlde wherein are declared the rare and singular vertues of divers Herbs, Trees, Plantes, Oyles and Stones, with their applications, as well to the use of Phisicke as of Chirurgery," 1596, brought £6 7*s*. 6*d*. "The Herball of J. Gerarde," 1636, 24*s*. "Select Observations on English Bodies: or Cures both Empericall and Historicall, performed upon very eminent Persons in desperate Diseases ..... now put into English by James Cooke," 1657. This was in original calf, and the catalogue stated "no portrait." The auctioneer was of the opinion that no portrait was issued with this edition. It realised £13.

AN INFANT KILLED BY CREASOTE AND A "COMFORTER."

IN the Hackney coroner's court the death of an infant, 13 weeks of age, was recently proved to be due to the following circumstances. The mother, the wife of a warehouseman, went out shopping, leaving the deceased alone with her two other children, whose ages were respectively eight and three years. The younger of these had seen his mother give the infant one of the objectionable rubber teats, known to ignorant mothers by the name of "comforters," and had also seen her dip it in a bottle of essence of aniseed before giving it to the baby to suck. The child of three proceeded to do this, but dipped the comforter in a bottle of creasote which stood on the mantelpiece where the aniseed was kept. The medical evidence given was to the effect that death, the immediate cause of which was bronchitis, had been accelerated by injury due to the creasote, and the jury returned a verdict of "Accidental death," the coroner making the observation that the case might serve as a warning to parents to keep dangerous things out of the reach of their children.

THE DESTRUCTION OF FLEAS.

To the Editor of THE LANCET.

SIR, Could any of your correspondents give an effective way of (1) destroying the pulex irritans: (2) keeping them off the person, the usually given methods having failed. A recent writer has stated that three parts of their life is spent on the ground, and anyone accustomed to stand by the bedsides of the sick poor can confirm this.

I am, Sir, yours faithfully,

Nov. 5th, 1910. MEDICUS.

SUPERSTITIOUS REMEDIES.

A CORRESPONDENT sends us the following list of "remedies," drawing our attention to the almost incredible fact that such superstitions still linger in out-of-the-way places in Ireland and Wales. The first five remedies are for epilepsy, and come from Roscommon:—

1. Where a person falls at the time of a first attack, if on a flagged pavement or in a court, at once lift a flag. Kill a fowl and cut a piece of the warm flesh. Place the bit of fowl with a silver coin in the hole and replace the flag, and there will be no return of the fit.
2. A child fell on a road on her way to school, having an attack of epilepsy for the first time. An old woman ran from her house and said "Don't touch the child." She then undressed the girl and taking the chemise she burnt it, then re-dressed the girl with a new chemise in place of the burnt one.
3. Dig a hole in the road where the person falls and put in a silver coin.
4. Procure the water in which a corpse has been washed and give a wineglassful to the patient three times a day. [This remedy was tried on the brother of the informant, but as he vomited the cure was of no avail.]
5. Procure the milk of a foal (not a mare), which is very rare, and give a teaspoonful three times a day.

For warts the following receipt is held good in County Mayo:—Cut 12 pieces of straw with the joints in the centre of each piece, place them in a hole in the ground, and as they decay the warts will wither.

For shingles an old Welsh gardener told his mistress that he was able to cure the affection by passing his hands over the affected parts, as he was the great-grandson of a man who had shot and eaten a bit of an eagle, which had given him and his descendants this miraculous power.

"*Hollins Cross.*"—The meat solution was analysed by THE LANCET and the report appeared in Vol. I., 1899, p. 240. According to Dr. Robert Hutchison (Food and Dietetics, London, Edward Arnold) it is made in the following way: Beef is chopped up finely and placed in jars, with its own weight of 2 per cent. hydrochloric acid. The mixture is heated in a Papin's digester for 12 to 15 hours with occasional stirring, till all the fibres of the meat are loosened. It is then rubbed up in a mortar to a fine paste and again heated under pressure for 15 to 20 hours. It is finally neutralised with carbonate of soda and made into a paste with water. The result is a fine "sludge" of finely divided meat fibre, part of which has been converted into peptone. One tin, which is recommended as a day's ration, contains half a pound and costs 2*s*. It is supplied by H. Poths and Co., 4, 5, 6, Bury-court, St. Mary Axe, E.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Nov. 4th–12th (London).—Ninth International Motor Exhibition.
,, 7th–12th (Cape Town).—Twelfth South African Medical Congress (1910).
,, 11th–19th (London).—Stanley Exhibition.

In 1911:—

Feb. 20th–25th (Cairo).—Fifth International Congress for the Blind.
May–October Dresden).—International Hygiene Exhibition.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September Brussels).—Exhibition of Fractures.
Sept. 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 24th–30th (Rome).—International Congress on Tuberculosis.
,, 25th–29th (Rome) Seventh International Congress of Dermatology and Syphilology.

October (Cologne).—International Congress of Criminal Anthropology.

In 1912:—
September (Prague).—International Congress of Radiology and Medical Electrology.
September (Berlin).—Sixth International Congress of Obstetrics and Gynæcology.
September (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913:—
(London).—Seventeenth International Congress of Medicine.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Papers:
Professor Robert T. B. Wild: Pharmacology and Therapeutics of Sulphur and some of its Compounds.
Dr. H. Hume Turnbull: The Therapeutic Use of the Digitalis Group.

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham): at 8.30 P.M.

Professor A. Powell: The Bentley-Taylor Method of Mounting Mosquitoes.
Dr. B. Bradley: The Biological Characteristics of B. Typhosus, with Special Reference to the Fermentation of Dulcitol and Cyobinose.
Dr. C. Bolton: The Effects of Diet upon the Formation and Healing of Acute Ulcer of the Stomach.
Dr. Firth and Dr. Ledingham: A Typical Chloroma.
Dr. Petrie and Dr. O'Brien: Experimental Production of the Carrier-state by Feeding.
Dr. Firth, Dr. Bainbridge, and Dr. Ledingham: Case of Fatal Infection associated with the B. aertryck.
Mr. S. G. Shattock and Dr. L. S. Dudgeon: Dried Mouse Cancer.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—H. G. Adamson, J. H. Sequeira), at 11, Chandos-street, W.: at 5 P.M.

Cases:
Dr. A. Whitfield: Parakeratosis Variegata (?).
Dr. H. G. Adamson: Pemphigus Foliaceus of 16 Years' Duration.
Dr. Graham Little: (1) Mycosis Fungoides (with sections); (2) Granuloma Annulare.
Dr. Winkelried Williams: Parakeratosis of Finger of 20 Years' Duration, following a Dissection Wound.
And other cases.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—H. J. Marriage, Sydney Scott), at 11, Chandos-street, W.: at 5 P.M.

Cases and Specimens:
Mr. Arthur Cheatle: Congenital Malformation of Pinna.
Dr. H. J. Davis: (1) Venous Thrombosis of both Orbits and Cavernous Sinuses, following Mastoid Disease; (2) Thrombosis of Internal Jugular extending to the Sternum in a Supposed Case of Enteric Fever with Mastoid Disease.
Mr. Sydney Scott: (1) Lateral Sinus Thrombosis developing after Operation for Acute Mastoid; (2) Specimen showing Otitic Retro-cerebellar Abscess.
Dr. Dan McKenzie: Infiltration of Both Auricles (? Chronic Lymphangitis).
Mr. C. E. West: Chronic Dermatitis of the Pinna due to Infection by Staphylococcus Aureus, under Treatment by Vaccine.
Mr. H. J. Marriage: Large Tubercular Polyp removed from the Middle Ear in an Injant aged 7 Months.
And other cases and specimens.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 P.M.

Paper:
Dr. Alfred C. Jordan: The Röntgen Ray Examination of the Œsophagus.
Dr. Stanley Melville: Demonstration of a New Tube Stand.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Clinical Meeting. Cases will be exhibited by Dr. Voelcker, Mr. Fairbank, Mr. M. Heath, Mr. D. Fitzwilliams, Mr. Ashdowne, Mr. Barker, Dr. J. W. Carr, Mr. C. Symonds, Mr. H. French, and Mr. W. Low.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Sir Rubert Boyce: Yellow Fever in West Africa (with lantern demonstration).—Dr. S. T. Darling: Autochthonous Oriental Sore in Panama.—Dr. R. F. Jones: Tropical Diseases in British New Guinea.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Pernet: Clinique (Skin). 5.15 P.M., Lecture:—Mr. T. C. English: Surgical Affections of the Stomach.

TUESDAY.—4 P.M., Dr. G. Rankin: Clinique (Medical). 5.15 P.M., Lecture:—Dr. F. de H. Hall: Lymphadenoma and Intermittent Pyrexia.

WEDNESDAY.—4 P.M., Mr. C. R. Nitch: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. A. Latham: The Administration and Value of Tuberculin in Various Forms of Tuberculosis.

THURSDAY.—4 P.M., Mr. P. J. Freyer: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. T. C. English: Gall-stones.

FRIDAY.—4 P.M., Mr. G. French: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Rupture of a Gastric Ulcer.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Pritchard: Medicine,

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Beddard: Practical Medicine.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. R. H. Cole: The Social Aspects of Insanity.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: The Cardinal Symptoms of Urinary Disease (Surgical).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An Address
ON
THE PROSPECT BEFORE THE MEDICAL STUDENT OF TO-DAY.

Delivered before the Medical Students' Association of the Belfast University at the Opening of the Session on Nov. 15th, 1910.

BY JAMES ALEXANDER LINDSAY, M.D. R.U.I., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE IN THE UNIVERSITY.

GENTLEMEN,—Two problems confront the medical student: How to pass his examinations and how to obtain a foothold in professional life. The former is for the moment the more pressing; the latter is likely in the long run to prove the more serious. Of medical education I do not propose to speak to-night. It is at present in a state of flux, passing through a stage of evolution which will probably have salutary results. We are beginning to realise that too much has been attempted in the past, and that some limitation and concentration of the field of study must be effected. We cannot in the course of a five years' curriculum make even of the most promising medical student a good physicist, a good chemist, a good botanist, a good zoologist, a good anatomist, a good physiologist, a good pharmacologist, a good pathologist, and a good clinician. The thing is impossible, even if Harveys, Sydenhams, Hunters, Pagets, and Listers were as common as they are, unhappily, rare. What is now becoming clear—and one wonders that there was ever any doubt upon the subject—is that the preliminary subjects of the medical curriculum must be shorn of much of their detail, must be taught with a due regard to the ultimate destiny of the student, which in 19 cases out of 20, at a moderate estimate, is to become a practitioner of medicine. Further, medical education must steadily keep in view its two indispensable objects—viz., to enable the medical student to acquire a secure grasp of the essentials of his art, both on its theoretical and its practical side, and to give him sufficient practice in scientific method—in other words, an adequate intellectual discipline and training.

ALTERNATIVES OPEN TO THE YOUNG MEDICAL GRADUATE.

But it is of your after-career that I wish to speak to-night, of the life-work for which you are now, with more or less industry and earnestness, preparing yourselves. When you receive your diplomas from the Chancellor you will feel a temporary glow of satisfaction—very natural and human and proper. But the glow will not last long. A great novelist once wrote a novel with the title "What will He do with It?" That is the question which you will be presently asking about your piece of parchment. Is it to be a magic key to unlock the doors of fame and fortune, or only a ticket to a back-seat in the gallery of an inferior play-house? Time will tell. Much depends upon circumstance and opportunity, but more depends upon the holder of the parchment. Speaking generally, five alternatives lie before the young medical graduate: 1. He may become a resident medical officer in a hospital. 2. He may become an assistant in a laboratory. 3. He may enter one of the public services. 4. He may become a ship's surgeon. 5. He may become an assistant in general practice.

I have not time to contrast these careers in any detail, but will content myself with a remark or two. If you can, if financial and other circumstances permit, select an opening which will enable you to continue your education. However great your diligence, however thorough your training, you will on graduation be conscious of many gaps in your knowledge, many limitations in your experience. Take time, if you can, for further observation and reflection—whether it be in a hospital or a laboratory, or, better still, in both. Let your knowledge settle and clarify, or, to vary the figure, let it ferment and bring forth new forms and fresh combinations. There is no time in life when the mind is more receptive than during the two or three years following graduation, when released from the burden and torment of examinations and fascinated by the expanding vistas of his art, the young medical man tastes one of the purest joys of existence.

If the services should early claim you, there will lie before you a career with many attractions, and never more desirable than to-day, but with some definite and not inconsiderable limitations, with which you should acquaint yourselves before making your choice. If you should become a ship-surgeon—and the desire of seizing the only opportunity of seeing the world which may ever arise is natural, and even laudable—I have one or two cautions to suggest to you. Take two or three voyages, and no more; and then return to *terra firma*. The experience gained on shipboard is rarely of much value; the financial gains are in most cases scanty; the habits formed are not the best preparation for future professional life. In some ships in which I have been a passenger the doctor's duties seemed to be almost confined to taking what one of them described to me as a "smell round" the steerage quarters in the morning, and arranging dances and theatricals for the young ladies in the evening. Unless the ship doctor is of quite unusual stiffness of moral fibre, he is apt to sleep too much, to smoke too much, to take too many whiskies-and-sodas, and to devote more attention to current fiction than to Osler or Taylor or Rose and Carless.

An assistancy in general practice may be either desirable in itself and lead on rapidly to a partnership and a secure position, or it may prove laborious, unprofitable, and disappointing. Some time ago I encountered on one of the cross-Channel steamers a graduate of this school who had settled in the East-end of London. He complained of the hardships of his lot. I remarked, "Well, at any rate you have got your foot on the first rung of the ladder." "Yes," he replied, "and it is a *very dirty rung*." No doubt the lower rungs of the professional ladder often leave a good deal to be desired in point of cleanliness, as well as in other regards, but perhaps a little hardship at the commencement of one's career is not an unmixed evil. Ὁ μὴ δαρεὶς ἄνθρωπος οὐ παιδεύεται, says the stern Greek proverb—if one may still quote Greek in these degenerate days—which may be roughly translated, "We are all the better for an occasional application of the rod." Where things are too easy and nature too kind, where the savage lies in the sun and lets the bread-fruit drop into his mouth, nothing much is achieved in the domain of character. A visitor to Barbados once saw a negro enjoying his ease and thus addressed him: "How do you manage to pass the time, Sambo?" "I just lie in the sun, massa, and let the time pass me," was the reply. That is not a good model for the medical profession, which its worst enemies have never called an easy life. The rough and the smooth come in most lives, and it is well when the rough comes early, before the heart is too faint and the brain too tired to bear it.

The young medical graduate may at the outset of his career be undecided what department of practice will ultimately claim his attention—whether general practice or one of the special branches—and hence, he may be in doubt how to shape his course. Here, I think I may suggest two guiding principles. If there be a decided taste for, and early selection of, some special branch—e.g., public health or ophthalmic surgery—it is probably wise that the young graduate should soon bend his energies to his future life-work. In the absence of such special taste or early choice the best course is for him to cultivate himself as widely as possible, to enlarge the field of his experience in many directions, to make his professional armour as complete as he can. Specialism is the great feature of modern practice. It is the necessary corollary of advancing knowledge and the growing complexity of our art, and it is idle to impugn it. But we all know the dangers of a too narrow specialism. I have heard of a throat specialist, consulted for a pharyngitis, who gave some excellent advice as to the management of the throat, but overlooked the fact that the patient was in the early stage of typhoid fever. Cultivate yourselves as variously as you can, and do not be in too great a hurry to terminate your period of preparation, your medical novitiate. "Tout vient à point à qui sait attendre," says the wise French proverb, which we very inaccurately translate, "Everything comes to him who waits," thus turning one of the truest of proverbs into one of the most false. Everything does *not* come to him who waits—far from it. But everything, or nearly everything, does come to him who knows *how* to wait, to him who spends the waiting time well.

FINANCIAL REWARDS.

Let us now look at the career which awaits you in the future—the career of medical practice—in some of its

general aspects. Is medicine, as some assert, an overcrowded, arduous, and ill-paid profession, with little certain leisure, heavy responsibilities, and a relatively poor prospect of attaining length of days? Or is this view unduly pessimistic? And first, as to the question of overcrowding. It can hardly be denied that during the last three or four decades there has been in most civilised countries an undue rush to medicine, that the supply has exceeded the demand. This rush has been even more marked in France, Germany, Italy, and America than amongst ourselves, and it has been contemporaneous with a notable dearth of candidates for the Church—a very significant circumstance. It is highly probable that if some of those whom I address had lived a generation earlier, instead of handling the scalpel, or the stethoscope, and attending to the sick, you would have been engaged in expounding theology, baptising infants, and joining happy couples in holy matrimony. Whether this involves your loss or gain is a question which I shall not attempt to determine. But I do not think that overcrowding of the medical profession is an urgent question in Ireland. Belfast, with a population of about 380,000, has 247 medical men on its register, of whom about 230 are in practice, which works out at about one medical man to 1650 people, and this is a proportion which is supposed to afford a reasonable prospect of a livelihood to the medical practitioner. Cork, with a population of 76,000, has 93 medical men on its register; Limerick, with a population of 38,000, has 35 medical men; and Londonderry, with a population of a little over 40,000, has 34 medical men. If we allow for those recently qualified and not yet in practice, for those engaged in special branches, such as lunacy or public health, and for retired veterans, these figures, though ample, are not excessive. The case of Dublin, with two Universities and two other qualifying bodies, is exceptional. In England the ratio varies greatly, as might be expected. For example, Sheffield has a ratio almost the same as that of Belfast, while Brighton has no less than one medical man to 600 people—a very high rate, but accounted for by more or less obvious reasons.

But granting that, speaking generally, the medical profession is somewhat overcrowded, are not other professions in a like case? The congestion at the Bar has long been notorious. Of those called to the Bar it might be truthfully said, "Many are called but few are chosen." A well-known judge said recently to a friend of mine that there were 10,000 barristers in England, and only work for 500. I cannot guarantee the accuracy of these figures, but my authority is good. Or take the scholastic profession. In the *Times* of Oct. 7th, 1910, there were some interesting figures regarding the overcrowding in this profession. Of 4836 students who left college in July, 1909, prepared for scholastic work, it was found that in the following October 38 per cent. had not secured permanent work as certificated teachers, while 31 per cent. had secured no work at all. Now, how many of the graduates of this school are unplaced three months after graduation? Comparatively few, I think, except those who are lying out, waiting for some appointment. The large majority find billets of some kind in a few weeks or months. I grant that the billets are not always lined with swan's down, that the work is often hard, and the pay rarely munificent. But billets of some kind are found with surprising rapidity. The young recruits of our profession, whatever be their hardships, do not at any rate join the ranks of the unemployed. They do not frequent soup-kitchens, or go on deputations to the Home Secretary, or cry out for a "living wage."

Is medicine an arduous, a hard profession? Certainly it is. That is one of its glories. You will have "to endure hardness," many of you at least, and it will be good for you. If you are not prepared to have, occasionally at least, a rough time of it, to rise often at the unwelcome tinkle of the night-bell, to leave the dinner-table sometimes before you have finished your second cigarette, to resign the joys of the links on occasion because the telephone summons you elsewhere, to encounter fatigue cheerfully and to face danger with a light heart, turn back before it is too late, for you have mistaken your vocation.

Is medicine an ill-paid profession? That is a question difficult to answer. No doubt we all wish that it were better paid. "I should like to possess riches," said the poet Shelley, "because I think I could use them well." That is what we all think. Now I do not believe that finance is a strong point of our profession. No profession does so much for nothing or is so often defrauded of its just dues. Our legal brethren understand these things better. When you compare a bill of law costs—magnificent in amplitude, rich in detail—with the modest reminder which the practitioner of medicine sends to his patients at Christmas-time, you will recognise that law has at least one point of superiority over medicine. Further, there are no great financial prizes in our profession. If any of you have the ambition to become millionaires you have not started on the right path. You had better give up medicine and turn your attention to rubber, or petroleum, or whisky. That some branches of our profession are systematically sweated by the public can hardly be denied; witness the Irish Poor-law service, where in some cases I am credibly informed that the salary barely covers the doctor's car-hire. Those who expect good service on those terms are expecting too much from human nature. Again, medicine has no comfortable sinecures, no snug posts with light work and good pay, where virtue may enjoy its ease and suffer no hardship.

But there is something to be said on the other side. The financial rewards of medicine, if seldom brilliant, are often substantial, and they are fairly secure. If the standard of remuneration is in many cases too low, the fault is largely with ourselves. With ourselves, too, might rest the remedy, but a too careful regard for the amount and the security of our financial rewards is, upon the whole, opposed to the traditions of the medical profession. Ruskin says that the doctor likes his fee well enough, but that he would rather lose his fee and save his patient than gain his fee and lose his patient. I hope this is true, and that it always will be true.

OPPORTUNITIES TO EXTEND KNOWLEDGE.

Let us turn to some wider considerations. Medicine offers you, gentlemen, a work which is in touch with the reality of things, which is in contact with nature at first hand. Law is man-made. Theology is trammelled by tradition. Medicine looks, or should look, at the facts of nature as they are. She can afford to lift "the Veil of Isis"—that "thick web of fiction which man has woven round nature," as Huxley says. You will be first and essentially practitioners of an art—the art of healing; but it may be the high privilege of some of you to extend the frontiers of knowledge, to sound a little more deeply the unplumbed sea of mystery, by which we are surrounded. Research is an essential function of modern medicine, and, rightly understood, it is worthy of every encouragement. The difficulty is to find your true researcher, the man who will not only *seek* but *find*. When you have got him, he is a very important person indeed, but there are a good many imitation articles in the market. You may be destined to extend knowledge, and as Bacon says finely, "We see that voluptuous men turn friars and ambitious princes turn melancholy, but *of knowledge there is no satiety*." The physician should also be a naturalist, and while man is his special field of observation, he must include in his purview everything which has a direct relation to man on his physical side, and that takes him far. Think of the revelation of the methods of nature, of her mysterious workings, which has come with the development of the comparatively new science of bacteriology. Our "invisible friends and foes" have become potent realities to us, and we are gradually learning how to avail ourselves of their assistance or how to guard ourselves against their attack. Think of the light thrown on the problems of mind by the stupendous advance in our knowledge of the anatomy and physiology of the brain. A great metaphysician of a bygone generation—the greatest of his time—once wrote a paper on the thesis that a knowledge of the structure of the brain could throw no light on the phenomena of mind. We smile now at such a contention. The tables are completely turned, and the metaphysician and the psychologist look to the physiologist and the physician for light and leading. It is hardly presumptuous to say that any true theory of human nature must come from the side of medicine. Two of the most eminent of modern philosophers—Wundt and William James—owe much to having laid the foundations of their speculations in the study of our art. Practise your art, then—this first and chiefly—but advance knowledge if you can. It is probable that important facts, unrecognised, lie around us, if we had eyes to see. I once heard a great preacher drawing a vivid picture of the miseries of human life, and he described a man dying on a mountain

"with, perhaps, the plant which might have healed him growing by his side"—a moving picture, rhetorical, but in essence true and with many applications. We fail to see many things because "there is a veil upon our eyes." See that you open your eyes as widely as may be, that there be not upon them the veil of prejudice or superstition, of sloth or carelessness.

Medicine offers you, further, a field which is ever extending its borders, ever touching life at more points. In the infancy of our art its attention was confined to the healing or alleviation of wounds and diseases. The famous leech in the "Iliad," Machaon, knew a good deal about plasters and ointments, purges and febrifuges, but he did not know how to prevent suppuration or ward off ague. He would have thought it most unreasonable to require such knowledge from him. It was at a much later date, in quite modern times, that the prevention of disease, now justly regarded as more important than its cure, became one of the essential tasks of our art. And how vast is the field of prevention, how far in this matter does practice lag behind knowledge? It is not too much to say that if all the knowledge which science now puts into our hands were fully utilised, if there were no financial or economic difficulties, nearly all infective diseases—that grievous brood of Furies which has pursued poor humanity from the dawn of history until now—would be banished or reduced to insignificant proportions in the course of a single generation. Then, in even more recent times, the promotion of health—the science of hygiene or eugenics—has become organised, and just now there is slowly rising above the horizon the fourth, and final, task of the art of medicine—namely, a care for the purity of the species, a thought for the interests of the unborn, a determination that, as far as may be, the stern word of the Hebrew Scripture shall no longer apply, that "the sins of the fathers shall *not* be visited upon the children." To heal disease, to prevent disease, to promote health, to see that the fountain of human life is not polluted at its source—these are your tasks, gentlemen. They are worthy of *you;* see that you are worthy of *them.*

MEDICINE AND SOCIAL EVOLUTION.

Medicine, again, may be fairly described as a profession which is growing in public esteem, and more and more approving itself to an age of which the ideals are largely utilitarian. The great discoveries of Pasteur and Lister, of Koch and Behring have profoundly impressed the imagination of the world. It has been recognised that in some important fields the veil was truly being removed from nature. Turning to another field, the spectacle of a regenerated Cuba, a Panama Canal with a moderate death-rate, a West Africa partially rescued from the scourge of malaria—all the fruit of applied medical science—has seemed to herald the dawn of a new era for humanity, when man might hope for a final victory over infective disease. And the success—still partial, but none the less ultimately assured—of the Anti-tuberculosis Movement amongst ourselves tells the same tale. In many fields medicine is steadily extending its scope. Only the other day England, following in sadly-belated fashion the example of continental nations, admitted the doctor to inspect her schools and scholars. He is not yet admitted to a similar duty and privilege in Ireland, but this cannot be long delayed. When that day comes, as come soon it must, and the doctor enters the primary schools of Ireland as an official with authority, he will find a fair field for his energies, and if his language should be a little warm, let us hope that the Recording Angel will be lenient, due account being taken of the nature of the provocation. Our profession is still much under-represented in Parliament, and we have still to wait for a Ministry of Public Health. If we had a solid phalanx of medical men in the House of Commons who would cry out for attention to the health of the people with the same energy as others cry out for *Dreadnoughts* and Territorials, it would be better for the nation. We spend £70,000,000 a year on defence—on men, ships, guns, and powder—and how much on an organised attempt to stem the tide of disease and improve the national physique? A mere song by comparison. The machinery for destroying life is much more elaborate and much more costly than that directed to its preservation and improvement. Why? The only answer which I can suggest is that we are still barbarians, with a thin veneer of civilisation; still heathens, with just a slight tincture of Christianity. Man is a fighting animal—especially the Irish man—and the fighting instinct has its uses and is not without its noble side. Yet it is probably destined ultimately to disappear, but not in our day.

Medicine is probably destined to take an ever-increasing part in the work of social evolution. The great task which lies before the twentieth century is the organisation of society upon a scientific basis. We have got to rid ourselves of the dead hand of a past which we have outgrown. We have got to open our eyes to the light which is now streaming in upon us from so many quarters, to avail ourselves of every fresh insight gained into the powers of nature, to make opinion and practice really accordant with fact and experience. In this great work medicine must take a prominent part. Problems such as those of infant mortality, the increase of insanity, the falling birth-rate, the hygiene of trades and occupations, physical education and eugenics, and many kindred questions lying at the very root of social efficiency, cannot be settled, cannot, let us rather say, even begin to be understood, without the intervention of medical science. The medical man is, no doubt, primarily a healer—that is his indispensable function; but he must also be an educator, a pioneer of progress, a social reformer, a leader of opinion. He possesses knowledge which is useful, not only in the sick room and the hospital ward, but in the school, the factory, the farm, the senate. He must spread the light. "There is no darkness but ignorance," says our great poet, and Schopenhauer speaks shrewdly when he says, "All ignorance is dangerous and most errors must be dearly paid. And good luck must he have that carries unchastised an error in his head unto his death."

THE QUALITIES OF THE MEDICAL PRACTITIONER.

Once more, medicine offers you a career which includes a certain ethical training and discipline. What do these include, and are they altogether on the right side? Well, I do not claim for our profession that it produces any exceptional proportion of saints or heroes. It does produce some—Dr. McClure does not stand alone; but let that pass. I should rather claim that as medicine sees things as they are—man and nature unveiled—as the medical man is in touch, close touch, with realities, he should be first and foremost a man of common sense, level-headed and discerning, sympathetic but not sentimental, helpful but self-respecting, and he should be specially on his guard against vagaries of thought, opinion, and practice. The history of our art, which is far too little studied, affords many warnings against the follies of medical practice, the fleeting fancies of the hour. The popular folly of the hour just now is that soured milk is a panacea for most of the ills that flesh is heir to, and that if we can only introduce a sufficient number of the *Bacillus bulgaricus* into our large intestine all will be well. And leaders of our profession and eminent scientific luminaries lend their sanction to rubbish of this kind. We shall see how long this fad will endure. Probably it will have a brief day, but when it has "mingled with the infinite azure of the past" there will still remain the fact that buttermilk *does* possess some useful nutrient properties.

But it is often hinted that our work tends to make us callous to suffering. Now, by an absolutely invariable law of human nature the frequent repetition of any impression weakens its intensity. Even the twentieth cigarette is not quite so sweet as the first or the second. The spectacle of disease and death is our daily portion. We come to regard them with comparative calmness. It could not be otherwise, and to quarrel with this fact is merely to tilt against human nature. Yet I think we may claim without presumption that the medical man's sympathy, so long as there is anything to be done, is rarely wanting. His instinct is to act rather than to talk, and perhaps he is not always sufficiently mindful of the fact that there are occasions in life when kind words mean a great deal. But medicine is essentially a sympathetic profession. The Bar can never shake off the taint of contentiousness. The priest is always to some extent a man apart. But the doctor is a man amongst men, whose business it is to help them, who stands by them in the hour of their extremity, who places whatever knowledge or skill he may possess at their disposal, and who is often sorry that he cannot do more. "We should neither weep nor laugh at human beings," says Spinoza, "but endeavour to comprehend them." I think our profession fulfils that ideal at least as well as any other profession. A very eminent living physician once said to me

that the most important quality for a practitioner of medicine was—what do you think?—skill? wisdom? courage? resource?—No; but *hopefulness*. Christian Science has played, and is playing, such vagaries before high heaven as might well make the angels weep, but it has done us one service—it has emphasised the importance of the mental factor in the treatment of disease, of the weight to be attached to the expectation of cure and the determination to get well. Hope is, indeed, the sheet-anchor of poor humanity in the dark hour of sickness and suffering, as in other dark hours. There are times in most lives when if it were not for hope—hope that the clouds will some day break, that the dark night will be succeeded by some brightness of dawn—where should we be? Therefore when you enter the sick-room beware of the clouded brow or the mournful voice. You must for the moment at least dismiss your own troubles if you wish to relieve the troubles of others. You must have "a heart at leisure from itself" if you would cheer other sad hearts. Hence, as a profession, doctors are cheerful men by a sort of necessity of the case, an inherited professional habit of mind, for which, perhaps, we deserve little credit. The "weeping philosopher" may have his uses in the world, but let him not attempt to practise physic.

STATE MEDICAL SERVICE.

One last topic I suggest to you, but it is too vast to be dealt with adequately at the close of an address. A proposal has recently been put forward for the nationalisation of the medical profession—i.e., the reorganisation of the medical profession as a department of the Civil Service. If this were effected, doctors would become servants of the State, they would be subject to the supervision, direction, and control of the State, and private practice would cease. Medical men would be distributed according to the circumstances of the case and the needs of the locality; overlapping and competition would come to an end, work would be more evenly distributed, remuneration would be more equally awarded, sweating of the profession would be abolished. It is an attractive programme, but the practical difficulties in the way of its realisation are enormous. I must just hint at one. The value of a medical opinion varies from something less than zero to any figure you like to name. How will the State adjust the corresponding fee? Yet the suggestion is one worth thinking over. It must be remembered that there is at present a strong disposition to extend the area of State action, and that this tendency is sure to grow. It is impossible to say with any approach to certainty what, in the future, the State may or may not do, what functions it may or may not undertake to discharge. An organised State medical service is not an impossibility. Amongst its advantages would be the adoption of the One-portal Method of entry into the profession—on the lines of the Staats Examen of Germany—a reform towards which medical opinion in this country is steadily tending.

In conclusion, let us not lend too attentive an ear to those Cassandras who would assure you that in selecting the medical profession you are choosing a hard and thankless lot. You will not have an easy life, but it will be an interesting one. You will make many friends, and you will meet with some gratitude—perhaps as much as you will deserve. The patient whom you cure, and the patient who gets well when you happen to be in attendance—the two things are not quite synonymous—will probably let the world know about it. Few of you will achieve wealth, but all of you will, I hope, have bread-and-butter, and occasionally cheese. You will be members of a great brotherhood, in which there is much fraternal feeling and not more jealousy than might fairly be expected under the circumstances. Your work will tend to keep you in touch with the progress of science and all the wonders which are yet to be. Some of you may even live to pay your daily rounds by aeroplane or dirigible, without too much risk to your neck. You will probably witness an ever-increasing victory of man over disease, the gradual lightening of the dark shadows cast by malaria and plague, tuberculosis, and typhoid fever. You may watch the gradual evolution of a true sanitary conscience in the nation, a conscience which will banish those plague spots in our civilisation—the slum, the fever-den, the sweater's workshop, the insanitary schoolhouse, the foul dairy. You may, if you use well your opportunities, "see life steadily and see it whole." Few men have a better "conning tower" than ourselves. And then, when you are nearing what Kipling calls "the end of the passage," you will probably feel that your work has not been wholly in vain, that the world is a little, even if only a very little, the better and the sweeter because you have lived in it

HEREDITARY CRANIO-CLEIDO-DYSOSTOSIS,

WITH A REVIEW OF ALL THE PUBLISHED CASES OF THIS DISEASE: THEORIES OF THE DEVELOPMENT OF THE CLAVICLE SUGGESTED BY THIS CONDITION.

BY DUNCAN C. L. FITZWILLIAMS, CH.M. EDIN., F.R.C.S. ENG. & EDIN.,

SURGEON IN CHARGE OF OUT-PATIENTS, ST. MARY'S HOSPITAL.

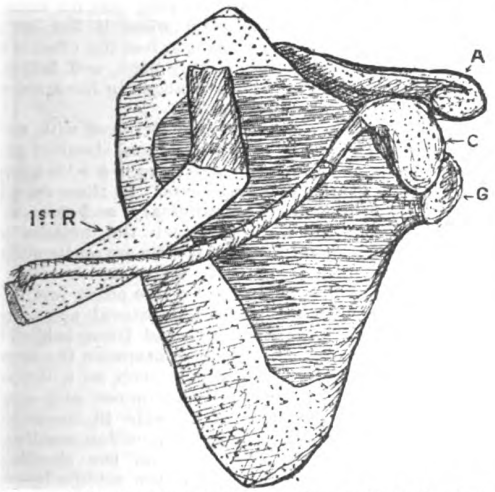
CONGENITAL defects of the clavicle occur and are usually associated with imperfect ossification of the cranial bones. This disease is undoubtedly rare, but its effects are so striking as to lead observers to place on record any instances which occur. So long ago as 1766 Morand noticed a typical example, but it was not till 1903 that Marie and Sainton accurately described the main features of this condition under the name of hereditary cranio-cleido-dysostosis. In 1905 Villaret and Francoz tabulated 45 cases, and reported an instance in which a mother and her three children were all affected. Two examples have come under my own observation, and I have been able to collect 58 others. A tabulated analysis of these 60 cases is appended to this paper. The records were often imperfect, but in all the identity of the condition is, I think, indisputable.

The first of my cases was a girl, aged 8 years, whose father, mother, brothers, and sisters were all free from deformity. Her right clavicle was in two portions, the division occurring at the junction of the middle and outer thirds. The sternal end was tilted upwards at its outer extremity, so as to over-ride the inner end of the acromial portion and form such a prominence in the neck as to induce the parents to seek treatment for the child. The acromial portion, owing to the weight of the limb, drooped and swung forwards and inwards, as in the ordinary fracture of the clavicle; its inner end lay under the sternal fragment and pointed upwards, backwards, and inwards, so that the right shoulder was lower, further forwards, and nearer the middle line than the left. An asymmetrical appearance was thus given to the upper part of the trunk when seen from in front, while posteriorly the vertebral border of the scapula on the affected side was more prominent than that of its fellow. The two portions of the clavicle were united by a ligament which became more evident on attempting to separate them. The point of the right shoulder could be forcibly adducted towards the sternum through a considerable distance, the point of disunion acting as the hinge. The prominence in the neck already referred to was not altogether due to the over-riding and tilting of the one fragment by the other, but was also accounted for by the fact that their adjacent ends were thickened in a very characteristic manner, contrasting markedly with the thin peg-shaped extremities seen in ununited fractures. There were no cranial, facial, dental, or other structural defects discovered. The arm movements were unimpaired. There was no history of trauma in infancy, nor had any pain or inconvenience ever been associated with the deformity. The lump had first been noticed when about 5 or 6 years, and was thought to have gradually become more prominent.

I have no hesitation in asserting that the condition in this child was a developmental defect. As regards the degree of deformity and position of the fragments, this case was typical of a class in which only one clavicle is affected. The position of the fragments may vary, so that the acromial overlies the sternal portion (Hultkrantz), or end-to-end fixation may be found (Carpenter).

The second case was that of a male child, aged three months, who died from marasmus. It had the large skull and shrunken-looking face so frequently mentioned in the reports of these cases. The ossification of the skull cap was extremely defective, the bones thin and translucent, the sutures widely open, and the fontanelles abnormally large, so that fully one-half of the vault was still in a membranous condition. In the shoulder girdle the scapulæ were well formed, but the clavicle on each side was represented by a

thin but distinct bar composed mostly of bone, but partly of cartilage. This bar, passing from the cartilage of the first rib, if not from the edge of the sternum, to the posterior end of the coracoid process, was attached to these points by short ligaments, and represented, I believe, the inner two-thirds of the clavicle. Unfortunately, no record was kept of the musculature of the two sides. Dr. F. J. Poynton and Dr. Reginald Miller showed this case to the Royal Society of Medicine, and it appears in the analysis as Case 51. My sincere thanks are due to these two gentlemen for being allowed to examine the specimens removed post mortem.



Sketch of the shoulder-girdle removed from Case 51. Shows first rib; A, acromion process; C, coracoid process; and G, glenoid cavity.

Other Features.

The features pathognomonic of hereditary cranio-cleido-dysostosis, other than those which are found in the clavicle, occur in the bones of the head and face. Particularly noteworthy are the shape and size of the skull, to which attention is drawn in 40 cases. In only 3 instances is the head stated to be normal; of the remaining 17 cases the notes are in many instances very incomplete on this point, and we may conclude that these characters either passed unnoticed or that no particular attention was paid to anything but the curious condition of the shoulder girdle.

The skull changes consist both in deficient and also in defective ossification of the bones forming the cranial vault. During infancy in this disease a large part of the vertex remains in its membranous condition. The anterior and posterior fontanelles are disproportionately large, or may, by the wide separation of the parietals, form one extensive fontanelle. This membranous area is further increased in size by an open metopic suture in front, and the absence of the interparietal portion of the occipital bone behind. This last-named piece of bone is developed in membrane, and is therefore affected in common with the other membrane bones of the vault; but as the remainder of the occipital bone is developed in cartilage it consequently escapes abnormality. As age advances this membranous area iminishes in size until the metopic suture, sagittal suture, and posterior fontanelle are obliterated by bone. This is usually complete by the twentieth year. Concurrently with this the anterior fontanelle shrinks until, a few years after the rest of the space, it is completely closed. Great delay in the closure of the anterior fontanelle is sometimes met, and in some cases it probably remains open throughout life; in Case 7 this fontanelle was "as large as the palm of the hand" at the age of 47, and in Case 24 was still unossified at the age of 56.

The delay in the transformation into bone of the membranous parts of the cranium is accompanied by excessive bone formation in those areas to which ossification has already extended, as if nature tried to compensate the unprotected membranous areas by increased bone formation in their immediate neighbourhood. As a result of this six prominent bosses develop on the vertex, arranged in three pairs, one behind the other, corresponding to the frontal, parietal, and occipital bones. The three bosses on the one side are separated from those on the opposite side by a broad median furrow, which is deepest in front and gradually becomes shallower as it extends backwards, while each symmetrical pair is separated from the other by a transverse furrow, one of which corresponds to the coronary and one to the lambdoidal suture; of these the anterior is the better marked, but is broader, shallower, and less evident than the median furrow. The formation of these bosses gives to the anterior part of the head an appearance resembling the hot-cross bun head occasionally seen in congenital syphilis, and this has caused observers occasionally to identify the condition with rickets, but in well-marked cases the frontal bosses are more prominent and the median furrow deeper than those found in syphilis and rickets.

A thickening analogous to these bosses is sometimes seen in the clavicle on either side of the interval between the two parts, as was strikingly demonstrated in my case. With this distortion of the normal outline of the head a corresponding variation takes place in the diameters of the skull. Where actual measurements are taken, the circumference, length, and breadth are all found to be enlarged, but not proportionately, the increase in breadth being greater than that in length, so that the skull acquires brachycephalic characteristics. Scheuthauer found on post-mortem examination of Case 24 a large number of Wormian bones situated in the sagittal and lambdoidal sutures, and that the spheno-occipital junction was markedly angular, with the convexity upwards.

In every case where the skull changes are present in a well-marked degree, they are accompanied by profound alteration in the skeleton of the face, the bones of which are said to be atrophied or undeveloped, the face itself frequently being described as small, and small it is when compared with the normal. The disparity in size between the small face and large head is frequently well depicted in illustrations which accompany many of the published records of this condition. Besides their diminutive appearance, the features are altered in a very characteristic manner. The supra-orbital ridge, partaking in the increased girth of the cranium, prominently overhang the orbits, while the bones bounding the orbits below, in common with the majority of bones of the face, are small and ill-developed and appear flattened or sunken in comparison. The roof of the orbit is sometimes depressed, thus causing some degree of exophthalmos. The general aspect of the orbit resembles that of a patient with a mild degree of hydrocephaly. The nasal bones are short, ill-formed, and not infrequently deviated to one or other side. Peculiarities, such as narrowness of the upper jaws or high vaulting of the palate, are mentioned 18 times, while irregular dentition is noted on 19 occasions. The reason for both these conditions is the same—namely, stunted growth of the superior maxilla, which gives rise to a V-like alveolar margin, thus greatly restricting the space available for the eruption of the teeth. Also with badly developed superior maxillæ and with overcrowding of the teeth, irregularity in the line of eruption is bound to occur. An exactly similar condition may be reproduced in children who suffer from naso-pharyngeal obstruction, where the disuse of the nasal air-passages entails lack of development of the maxilla, narrowing of the palate, and overcrowding of the teeth.

Various suggestions have been offered to explain these facial peculiarities—fœtal rickets occurring at the second or third month, and arrest of growth of the zygomatic arch; but most authors appear to regard lack of development of the facial and cranial bones as due to the same cause. Of the first two views nothing need be said. The last is easily shown to be fallacious, for not only are the bones of the face preformed in cartilage, whereas those of the vault are not thus outlined but are developed solely in membrane, but also a similar appearance is reproduced without the action of this disease by any condition in which there is delay in the closure of the vault of the skull, such as in the common forms of hydrocephaly. Because the increased intracranial bulk normally causes the cartilaginous base to expand and develop, but where the vertex remains unclosed, increased volume is readily accommodated by a separation of the bones of the vault, which "open like the petals of a flower," while the basal portions undergo a bending at the lateral margins, causing an angle to appear at the central part in the neighbourhood of the spheno-occipital junction, as was

noted in Scheuthauer's case. Want of expansion at the base of the skull must necessarily entail a lessened growth in the bones, which are firmly attached to this part of the cranium, hence the changes found in the nasal bones and superior maxillæ. In the lower jaw, however, which is not thus firmly attached, the stunting influence is less potent, and as we should expect, the face is frequently mentioned as being prognathous or the lower jaw is reported as underhung (Cases 45 and 54). Therefore the lack of development of the facial bones is secondary to the maldevelopment of the cartilaginous base, and has not a primary pathological significance.

I looked through the numerous skulls in the Museum of the Royal College of Surgeons of England in the hope of finding a skull with these characteristics among them, but was quite unsuccessful, an indication of the rarity of the condition.

The hereditary nature of this affection, insisted upon by Gegenbaur as long ago as 1864, although denied later by Gross, was fully recognised by Marie and Sainton when naming the disease by the title under which it is now known, and is conclusively proved by a consideration of this series—eight families producing no less than 31 affected individuals. In Case 17, not included in the above number, the father and brothers are said to be similarly affected, but no details are given. There can be little doubt that if the immediate ancestors and descendants of many other cases had been examined, this hereditary tendency would be even more clearly demonstrated. Transmission evidently is possible from parents of either sex, for 5 mothers and 3 fathers transmitted it directly to 23 children. I can find no evidence from the records of transmission to the third generation, but one must bear in mind that, among hospital patients, even with easily recognised and popularly familiar conditions, information as to the grandparents is rarely obtained.

The two sexes seem to be affected with equal frequency, 28 instances occurring in females and 26 in males; in 6 no mention was made of the sex of the individual.

Muscles.

The state of development of the muscles acting on the shoulder girdle has been noted by many writers, their superficial situation enabling accurate observation to be made; in a few exceptional cases opportunities have arisen for post-mortem examination. In my first case the muscles, as far as I could tell, presented no abnormality. I was not present when the specimen from the second case was removed, and unfortunately no note was made of the development and relationship of the various muscles.

The sterno-cleido-mastoid muscle seems to vary very much with the state of development of the sternal portion of the clavicle. When that portion of the bone is well represented the muscle is normal; but where there is only a small rudiment of bone present, the clavicular head of the muscle is reduced to a thin band partly attached to the bone and partly to the ligament prolonging that outwards. The sternal head of the muscle is always much less affected than the clavicular head (Kappler).

The clavicular portion of the trapezius, having no outer end of the clavicle for its insertion, is very frequently absent (Case 26), the muscle only coming as far forward as the tip of the acromion (Gegenbaur). It may, however, be present and find attachment to the coracoid and the ligament extending to that process of bone from the sternal portion of the clavicle (Scheuthauer).

The fibres of the deltoid muscle appear to be unaffected, but dissection shows that the anterior fibres are frequently lacking or only represented by a few fasciculi which take origin either from the inner border of the acromion process or from the fibrous band already referred to. In Shermann's first case the deltoid and infraspinatus muscles were very feebly developed. The posterior fasciculi of the muscles are well developed; and Villaret and Francoz noted enlargement of the tubercle on the spine of the scapula, and attributed its growth to the abnormal and compensatory activity of these fibres.

The clavicular head of the pectoralis major is usually present, but is feebly developed when the sternal portion of the clavicle is small; it was completely absent in Case 26. The chondro-sternal portion remains normal. There is some doubt as to the presence of the subclavius muscle; Gegenbaur, Kappler, Villaret and Francoz all question its existence, even where the two portions of the clavicle are well developed, and they consider that the movements of the bone are due to the action of the other muscles inserted into it. Scheuthauer, however, in the course of his dissections found the muscle hypertrophied and inserted into the under surface of the ligamentous representation of the clavicle. The deeper muscles seem unaffected.

In spite of the abnormal condition of the muscles, ordinary movements are uninterfered with. Many writers mention that the patients themselves were totally unaware of anything unusual, and Carpenter's cases had reached adult life, performing strenuous work, without noticing any disability. An illustration is published of a boy balancing himself on his hands with his feet in the air, showing that the shoulder girdle may retain its strength even when it has lost its rigidity. Other cases, however, seem to feel the effect of the condition, their arms becoming rapidly tired, and fatigue in the shoulders, after carrying her baby about in her arms, was complained of by one woman (Case 7).

But if the normal movements are uninterfered with, movements which are quite foreign to the normal shoulder girdle are allowed, especially in cases where there is a wide interval between the ends of the two fragments. In these cases the range of movements is truly extraordinary, and seems to be only limited by the distance to which the muscles will stretch. In the published illustrations, the favourite attitude in which to depict these cases is with the shoulders in apposition in the middle line in front of the chest just below the chin, giving a most bizarre and unnatural appearance. If when in this position they are viewed from behind, the upper part of the trunk resembles in appearance the narrow-shouldered outline seen in an animal such as a dog or a horse, in which there is no clavicle to prop out and support the shoulders. With the arms at the side in the ordinary position of rest the shoulder assumes the position usually seen in fractures of the clavicle—the point of the shoulder is lowered, swung forward, and is nearer the middle line than is normal. The scapula not being propped out, the anterior portion comes to lie in apposition with the chest wall, a winged appearance being produced by the prominence of the vertebral border. The humerus is slightly abducted and directed away from the side. This deformity is the more noticeable when the condition is unilateral and comparison can be made with the sound side. By pressure on the upper costal arches the position of the scapula just described may have some influence in producing the depression, so often noted, in the middle and lower parts of the sternum.

Clavicle.

Hereditary cranio-cleido-dysostosis is a condition which affects those bones which develop wholly or partly in membrane. For this reason it throws some light on the developmental origin of bones about whose morphology there still exists some doubt. It is interesting, therefore, to see what is the result of the dissection made by this disease upon the clavicle. The following table shows the incidence of the condition on each side throughout the 60 cases:—

	Left.		Right.
Both clavicles absent, 6 cases	—	.....	—
One clavicle alone absent	2	.....	0
One bone alone defective	1	.....	3
Sternal end alone represented	23	.....	27
Acromial ,, ,,	1	.....	2
Both portions present, but ununited	14	.....	17
Both portions joined, but showing by angling, notching, or arching, formation from two parts	5	.....	2
Ligament prolonging inner end outwards	13	.....	11

From this we see that throughout the series both the clavicles are totally absent on six occasions. Twice the bone is completely absent from the left side, the right bone being more or less represented; but the right bone is invariably present in some degree if there is any representation of the left.

The table also shows that when the bone is defective but not altogether wanting, the commonest abnormality is the absence of the outer or acromial portion, with the presence in a varying degree of the inner or sternal portion. This occurred 23 times on the left and 27 on the right side. Frequently the sternal end is fairly well developed, sometimes it survives only as a small cartilaginous nodule; in every case it is attached near the upper part of the manubrium sterni. With five exceptions (Cases 17, 21, 34,

No.	Name of reporter.	Sex and age.	Family history.	Head.	Clavicles.	Aspect and intelligence.	Remarks.
1	Abram.	M. 16	—	Head broad and bossed.	Only small nodules articulating with the sternum on each side, connected to a well-developed coracoid process by strong fascial bands representing the costo-coracoid membranes, to which the muscles are attached. The subclavius muscle is absent.	—	Dentition irregular; no episternal notch; manubrio-sternal junction opposite the attachment of the third costal cartilage.
2	Still.	M. 6½	Mother died from tuberculosis. Two other children healthy.	Head large and broad; anterior fontanelle 4¼ by 3½ inches.	Sternal ends present on both sides, more developed on the left; acromial portions absent.	Did not talk till 3½.	Face peculiar, nose flattened, terminal phalanges of thumbs short and nails curved. Walked late.
3	Seymour Taylor.	M. 20	—	Sketch shows head normal.	Sternal ends present and sterno-mastoid muscles attached thereto. Some attempt at development of the acromial end. Strong fibrous tissue representing the costo-coracoid membrane.	Intelligent.	—
4	Walsham.	M. 11	—	Head typically rickety; fontanelle unclosed.	Sternal two-thirds present on both sides, acromial one-third absent. Fibrous tissue passes from the sternal portion to the coracoid process.	—	—
5	Marie and Sainton.	M. 39	Father and mother well. Mother had six children, one premature. The patient had two children, the elder No. 6; the second died from convulsions at 2½, his head being deformed and open, like his brother, No. 6.	Head very large laterally; frontal and parietal bosses; both fontanelles open.	On the left side sternal end is deeply situated and small. On right side the two halves separated two fingers breadth.	Good.	Face small, nose depressed and deviated to the right; face prognathous, orbits overhanging. Dentition irregular; cleft palate; sternum depressed; genu valgum. Died from hemiplegia; never had syphilis.
6	,,	M. 12	Son of No. 5.	Head large, broad, and bossed; anterior fontanelle open.	Left side, two halves united by fibrous tissue. Right side, sternal part absent, the acromial part ending above the coracoid.	Poor.	Face small; dentition irregular; palate narrow and pointed.
7	,,	F. 47	Father died from paralysis, and mother from exhaustion. Nine children, seven alive and well.	Head large, broad, and bossed; anterior fontanelle and sagittal suture open.	Sternal portions only present in a cartilaginous state 3 cm. long; acromial portions absent.	Good; height, 1·46 metres.	Narrow arched palate; teeth shed; genu valgum; unaware of any abnormality of shoulders. Never had syphilis.
8	,,	F. 10	Daughter of No. 7.	Large head; frontal, parietal, and occipital bosses; anterior fontanelle persistent.	Sternal portions only present.	Normal.	Narrow arched palate, late dentition; flat feet, scoliosis, genu valgum.
9	Carpenter.	M.	A son 16 and a daughter 5, normal.	—	Bones on both sides in two halves. Sternal portions 3 inches long united by ligament 1½ inches long; sternal part overrides the acromial part.	Feeble development.	Unaware of any abnormality; sternal depression.
